Record of Public Comments Received During the Public Review and Comment Period on the Wisconsin DNR Draft Wolf Management Plan

The public review and comment period began on November 10, 2022, and concluded February 28, 2023, at 11:59pm CST. The comment period was initially announced via department news release on November 10, 2022. On January 4, 2023, an extension to the comment period was announced via department news release. On February 24, 2023, the department issued another news release with a reminder and last call for comments. The draft plan was made available on the department's wolf management plan webpage at the beginning of the comment period. Any member of the public wishing to share their thoughts on the draft plan could do so via an online comment tool, email, or regular mail. The department also hosted a public listening session on February 7, 2023, at which public comments were recorded verbally. Verbal comments collected during a February 18, 2023, public meeting hosted by the Wisconsin Wildlife Federation were provided to the department and also added to the record. All public comments received during the comment period are given equal consideration regardless of the avenue of submission. The department will review and consider all comments to inform potential revisions to the draft wolf management plan.

The following is a compiled record of the approximately 3,500 public comments received via all avenues of submission during the public comment period. Of these, approximately 71% of commenters indicated they were Wisconsin residents, 23% indicated they were nonresidents, and 6% did not indicate their residency. Over 72% of comments included a name while the remainder did not. Of those providing a name, approximately 110 individuals submitted more than one comment (most often two similar comments via different avenues of submission). There was no limit on the number of comments an individual could provide.

Note: We have attempted to redact all personal contact information and any inappropriate language within the comments; otherwise, comments are provided verbatim as submitted. Comments received via email attachment and regular mail have been grouped according to the submitter type. Verbal comments included comments provided by tribal representatives, Wisconsin legislators, stakeholder organizations, and individual members of the public; these comments are provided in the order they were given to maintain context with other comments. Finally, comments provided via the online comment tool are shared in chronological order of receipt.

Bad River Band Of Lake Superior Tribe Of Chippewa Indians

CHIEF BLACKBIRD CENTER

P.O. Box 39 • Odanah, Wisconsin 54861

February 27, 2023

Adam Payne
Secretary
Wisconsin Department of Natural Resources
101 S. Webster Street PO Box 7921
Madison, WI 53707-7921

Re: Comments on the Draft Wolf Management Plan

Dear Mr. Payne,

The Bad River Band of Lake Superior Chippewa ("Bad River" or "Band") respectfully submits the following comments to the Wisconsin Department of Natural Resources ("WDNR" or "Department") on its Draft Wolf Management Plan issued on November 9, 2022.

The Bad River Band is a federally recognized tribe in Northern Wisconsin, located wholly within the Lake Superior Basin and majority within the sub-basin of the Bad River – Mashkiiziibii – for which our Tribal Nation is named. The Bad River Band and its people maintain a reciprocal relationship with the natural environment. Anishinaabe people see the waters, trees, animals, plants, birds, and even the air as an extension of a large community. This community is at the center of Anishinaabe culture and life. The Band has a solemn responsibility to preserve our homeland, our environment, our culture, our treaty-protected resources, and our distinct lifeways for the coming seven generations.

Ma'iinganag (wolves) are of great significance to the Anishinaabe people. They are a clan animal, and part of the Anishinaabe creation story. Through the creation story we are taught that Ma'iingan and the Original man are brothers, tasked to walk side by side, naming all things. Once completed, the creator told the brothers that they must separate and walk different paths, but that their fates would be forever linked. Both would be feared, respected, and misunderstood by the people that would later join them on earth. It is our responsibility as Anishinaabe to protect Our Brother, Ma'iingan, for what happens to one shall happen to the other. It is for these reasons that the Band objects to the hunting of ma'iingan and has provided comments for the WDNR to review for a more inclusive wolf management plan.

Miigwech,

M. Daniel Wiggins Jr.

Position Statement on:

Wisconsin Department of Natural Resources' Draft Wolf Management Plan

By Taylor Parker-Greene,
Wildlife Specialist
For the
Mashkiiziibii Natural Resources Department (MNRD)

To: Randy Johnson, Large Carnivore Specialist
WI DNR, 107 Sutliff Ave., Rhinelander, WI 54501

We would first like to acknowledge and express our gratitude for the efforts involved in updating the Draft Wisconsin Wolf Management Plan by all Wisconsin Department of Natural Resources (WDNR) staff, as well as the committee members and tribal representatives who played a role in its contents. Although we believe this draft plan is a step in the right direction towards more acceptable ma'iingan (wolf) stewardship, we the Bad River Band of Lake Superior Tribe of Chippewa Indians (Mashkiiziibii) cannot in good nature support the killing of Our Brother, Ma'iingan.

Wolves are sacred beings and of great importance to the Anishinaabe people. In the Anishinaabe creation story, it is told that ma'iingan and the Original man walked the earth together, naming all things.

> "It is often said they came to be like brothers, [while] others contend that even this powerful bond fails to capture the full nature of the relationship, saying that Wolf and Man were really one being, parts of a greater whole. Thus, it must have come as a surprise or a shock when they completed their travels and returned to the Creator, to be told, 'From this day on, you are to separate your paths. You must go your different ways. What shall happen to one of you will also happen to the other. Each of you will be feared, respected, and misunderstood by the people that will later join you on this Earth' (The Mishomis Book, Edward BentonBanai, 2010). In many ways, this teaching of intertwined fates forms the ultimate foundation for the relationship between Anishinaabeg and ma'iinganag."

> (Ma'iingan Relationship Plan 1837/1842 Ceded Territory)

Bad River Band Of Lake Superior Tribe Of Chippewa Indians

CHIEF BLACKBIRD CENTER Box 39 • Odanah, Wisconsin 54861

The Bad River Band affirms its wish to engage in technical reviews and adaptations with the State. We believe this communication is vital to the protection of resources for which the Plan acknowledges "keystone species such as wolves are an important component of a healthy ecosystem"; a responsibility reflected in this letter. MNRD outlines what we see as successes in the Draft Plan as well as present comments we take issue with and request the State thoroughly analyze and address before a final plan is completed.

MNRD supports these elements of the Draft Wolf Management Plan:

- The decrease in harvest registration reporting time from 24 hours to 8 hours. This decrease in reporting time will increase the WDNR's ability to successfully monitor harvest data, allowing a more timely zone closure.
- Zone-specific licenses, allowing the number of licenses issued to be tailored to each zone dependent on that zone's specific objectives each year.
- The removal of the arbitrary numerical population management goal of 350 Wisconsin wolves.
- The acknowledgement of tribal nation treaty reserved rights in and around our tribal lands and ceded territories regarding wolf stewardship.
- The addition of subzones around tribal reservations. This will help to maintain viable wolf packs on tribal reservations (please see the related caveat in the modifications section below).
- The inclusion of a social science survey released with the Draft Plan – even if public views are omitted or not accurately represented throughout the plan, such as: opposition to specific methods of harvest like hounds (64%) or traps (70%), feelings that hunting wolves is unnecessary (62%) or culturally offensive to Native American tribes (57%). (Public Opinions Regarding Wolves and Wolf Management in Wisconsin)
- The recognition of the important ecological role wolves play in our ecosystems.
- The continued importance of education and outreach, specifically in regard to wolf conflict and mitigation efforts.

MNRD recommends the following additions and modifications in order to strengthen the Draft Wolf Management Plan:

- MNRD strongly opposes the harvest of Ma'iingan and believes legislative changes should be pursued to revoke Act 169.
    - The department can choose to restrict the implementation of lethal methods by setting the quota to zero.

  - Wolves are self-regulating, and do not need to be killed in order to keep their numbers under control.
- If it is the WDNR's attempt to respect tribal nations, then we believe the subzones around tribal reservations should be there to protect residential wolf packs and should be zero-take areas.

  "Mashkiiziibii has sovereignty over the reservation and holds rights to hunt, fish, and gather in the ceded territory, which makes up roughly the northern third of modern-day Wisconsin. Ma'iingan does not recognize human political boundaries. Mashkiiziibii Ma'iingan research dating back to 1996 shows that reservation wolves regularly travel off reservation."

  (Mashkiiziibii Ma'iingan Relationship Plan)

  MNRD staff have put in a great deal of effort over the years to mitigate any potential wolf threat to livestock owners by providing and installing non-lethal methods, such as game cameras, fladry, and flashing lights, in order to protect and safeguard our 4 residential wolf packs within the 6-mile buffer zone surrounding the reservation. This management zone and those around other Wisconsin reservations (which you can find more about in the attached Mashkiiziibii Ma'iingan Relationship Plan) are recognized, regarded, and in collaboration with agencies such as the WDNR and Animal and Plant Health Inspection Service - Wildlife Services (APHIS-WS). Tribal representatives are to be notified and given the opportunity to investigate any potential depredation event with APHIS-WS professionals and the landowner. This approach best reflects the adaptive management approach that the Draft takes and the chance for meaningful technical reviews and adaptions considering:

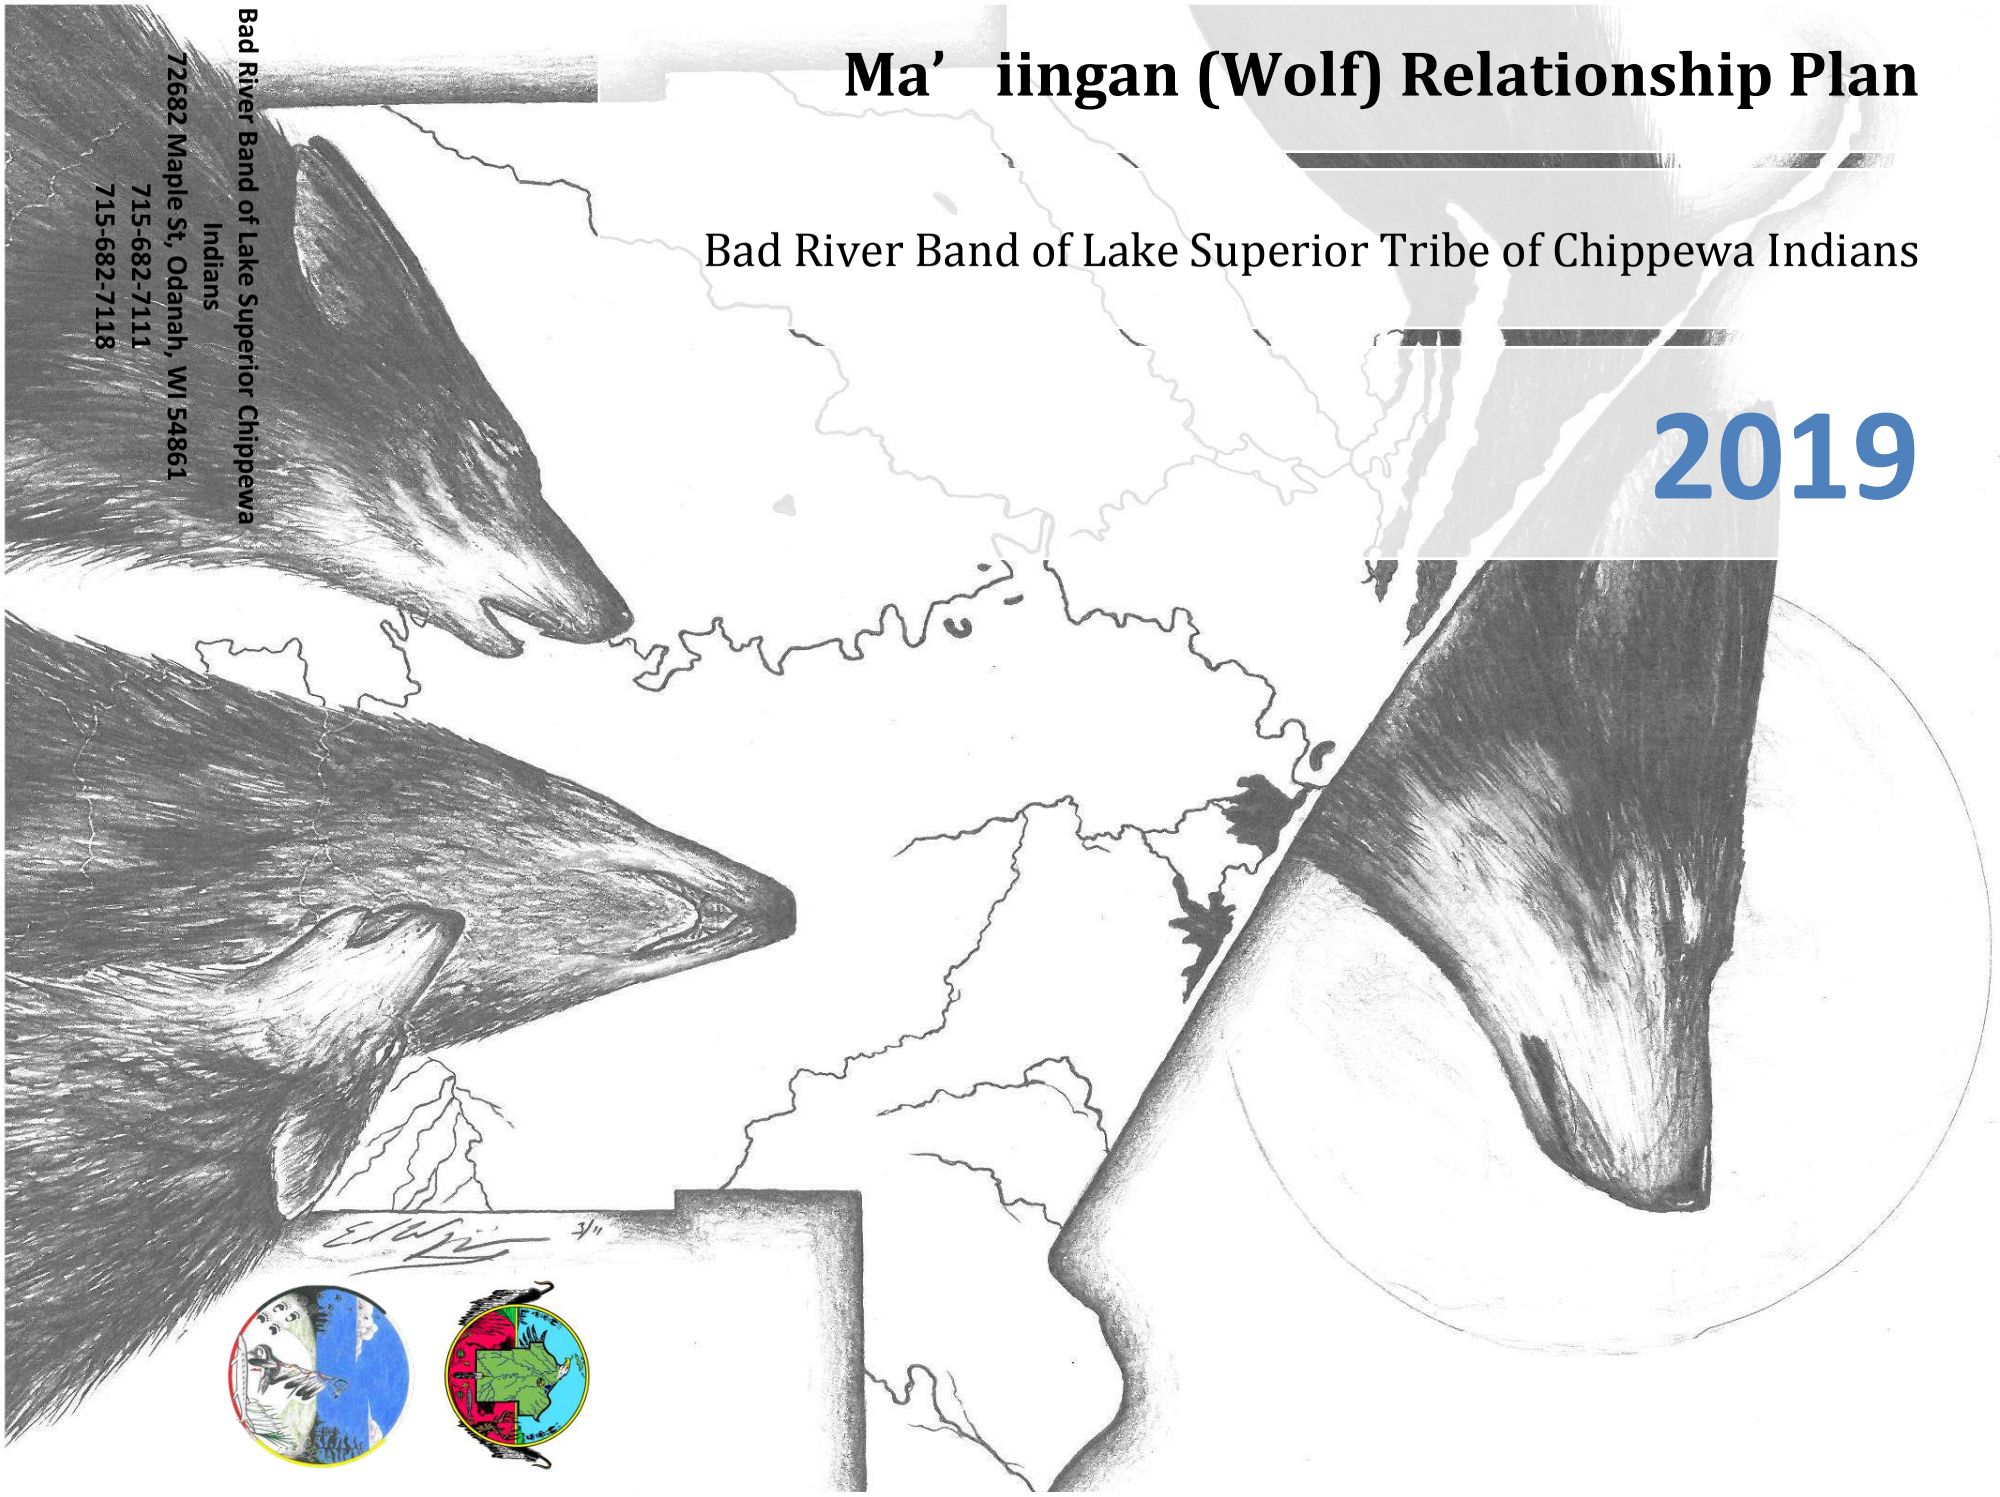
  1. Subsistence harvesting resources, especially:
  2. Effects on seasonal uses of resources that are connected with Reservation lands;
  3. Public health, including CWD and transmission paths (see point 6 below); and
  4. Federal trust responsibility and authority to manage land and wildlife consistent with Treaty relationships and authorized management plans.

- Although we recognize the decrease in reporting time from 24 to 8 hours is a step in the right direction, based on current technology, we believe the reporting time should be reduced even further to avoid any potential overtake risk.
- MNRD opposes hunting with hounds. Hounding it is extremely unethical and largely unsupported (64%) by the general public. We believe this practice should be deemed illegal.
  - Hound training season puts undue stress on wolves during rearing season and should be limited to the open wolf harvest season.

  - At a minimum, MNRD believes that hound hunting should be restricted from tribal reservation subzones, as well as national forests.
    - If hounding is not restricted from tribal reservation subzones (1b), a protocol should be put in place for not if, but when hounds inevitably enter reservation boundaries. The tribe should be notified immediately, and there should be repercussions for any wolf harmed within the boundaries of the reservation.
  - There should be no payout to hunters for hounds lost to wolves. Hunters who choose to hunt with hounds do so at their own risk and with the knowledge that they are putting their animals in highly dangerous situations. The state should not be responsible for the reimbursement of a lost hound.
- Consistent with the adaptive management approach of the Draft Plan, a priority in subzone 1 is non – lethal management. The lethal "management" of wolves as an attempt to curb livestock depredation has been largely disproven as an affective measure in scientific literature and this misinformation should not be presented to the public as though it does. Non-lethal preventative measures (e.g., guardian dogs, donkeys, fladry, and flashing lights) have led to greater conflict mitigation results and should be more highly emphasized within the plan (The effectiveness of livestock protection measures against wolves (Canis lupus) and implications for their co-existence with humans, Estimating wolf abundance with unverified methods, Carnivore conservation needs evidence based livestock protection).
  - The killing of a wolf in effort to prevent livestock conflict, may actually increase livestock vulnerability as the wolf pack has the potential to become unstable, leading to the pack seeking easier or more accessible and reliable food sources.
  - The state should provide funding to livestock owners in highly populated wolf areas for non-lethal control methods (as suggested above). The state should only reimburse for livestock loss when proper measures have been taken and proof of preventative methods can be verified.
- Wolves play an important role in preventing and controlling the spread of CWD in cervid populations. Waawaashkeshi (deer) are an exceptionally important food source for the Anishinaabe people, and the threat of CWD entering treaty-ceded territories and reservation lands is real. For this reason, we believe that any zone with increasing CWD numbers should result in a no hunt zone for at least 1 year in attempts to control and mitigate the spread of CWD throughout the state.
- Overharvesting and poaching should be taken seriously by WDNR, and we advise that the number of overtake be removed from the following year's harvest numbers.

CHIEF BLACKBIRD CENTER Box 39 • Odanah, Wisconsin 54861

- In addition to the current Wolf Management Plan Committee, we believe leading carnivore scientists should be involved in the annual review meetings. We also suggest that current literature be provided to and reviewed by all members prior to meetings.



Overall Rating: 6

Mashkiiziibii believes that the Draft Wolf Management Plan needs to be further developed, and the overwhelming number of changes suggested by tribal nations and the general public should be taken into serious consideration before the Plan can be approved.

Major Findings and Conclusions

I. Within Mashkiiziibing (Bad River Indian Reservation), including tribal lands on Mooninwaane'akaaning Minis (Madeline Island), Ma'iinganag is listed as a "Tribally Protected Species."

II. Classification of Ma'iingan and the contents of this relationship plan will be revisited by the Tribal Council and Mashkiiziibii Wildlife Program (MWP) every 5 years or sooner if deemed an emergency by Mashkiiziibii Tribal Council and MWP.

III. The Mashkiiziibii Wildilfe Program honors Ma'iingan and guides its actions based on Traditional Ecological Knowledge and scientific knowledge.

IV. The Mashkiiziibii Wildlife Program will not manage Ma'iinganag at a specific number, but will work with humans in a way that fosters human-wildlife coexistence on and around Mashkiiziibing. MWP has set a minimum Ma'iingan population goal: at least three packs within Mashkiiziibing, as has historically been the case.

V. The Mashkiiziibii Wildlife Program will continue to coordinate Ma'iingan conservation activities with tribal, state, and federal agencies as well as private landowners, to ensure the future of Ma'iinganag in Mashkiiziibing, in the state of Wisconsin, and in the Great Lakes Region.

VI. The Mashkiiziibii Tribal Wildlife Specialist is responsible for coordinating livestock or Ma'iingan mortality co-investigations within the exterior boundaries of the reservation and within the six mile buffer zone surrounding Mashkiiziibing.

VII. Any conflicts with Ma'iinganag within Mashkiiziibing or within the buffer area of Mashkiiziibing shall be reported to the Mashkiiziibii Wildlife Specialist within 24 hours of occurrence by either the individual involved in the conflict or by the immediate responding agency (WDNR or USDA-WS) dependent on location of incident.

VIII. In the event that a dead Ma'iingan is found anywhere in Mashkiiziibing or within the six mile buffer zone surrounding the reservation, the Mashkiiziibii Wildlife Specialist must be notified immediately by

either the individual that found the carcass or by the immediate investigating agency (WDNR or USDA-WS).

IX. If Ma'iingan is incidentally trapped, it shall be released immediately, if alive. If Ma'iingan is found to be dead, it shall be turned in and reported immediately to the Mashkiiziibii Wildlife Specialist.

X. The Mashkiiziibii Wildlife Specialist can assist in seeking livestock reimbursement from the state or federal agencies after a loss to a predator and MWP can offer carnivore coexistence consultation and free rental deterrent devices.

XI. MWP and the Bad River Tribal Council have placed a moratorium on collaring Ma'iingan, based on concerns for the ethical, scientific, and cultural appropriateness or lack there of in this research practice. Instead, MWP will work to understand reservation Ma'iinganag through track, scat, howl, and flying surveys as well as reports from tribal members.

Acknowledgements

Miigwech to The Creator for giving us a brother in Ma'iingan. Miigwech to Ma'iingan for teaching and protecting us. Miigwech to Lacey Hill-Kastern for creating the original Mashkiiziibii Ma'iingan Relationship Plan and for mentoring and training Abi Fergus. Miigwech to the Mashkiiziibii community for helping to shape this plan and for teaching Abi Fergus. Miigwech to Edward Benton-Banai and Joe Rose Sr. for teaching us about Ma'iingan. Miigwech to Edith Leoso, Anthony Corbine, and Stephanie Julian for providing knowledge for this plan. Miigwech to Suzi Smith of the Mashkiiziibii Natural Resources Department for reviewing the plan. Miigwech to Erick Arnold of the Bad River Legal Department for reviewing the plan. Miigwech to Philomena Kebec, Peter David and Travis Bartnick of the Great Lakes Fish and Wildlife Commission for reviewing the plan. Miigwech to Mashkiiziibii Tribal Council for reviewing and approving the plan.

Goal of the Mashkiiziibii Ma'iingan Relationship Plan

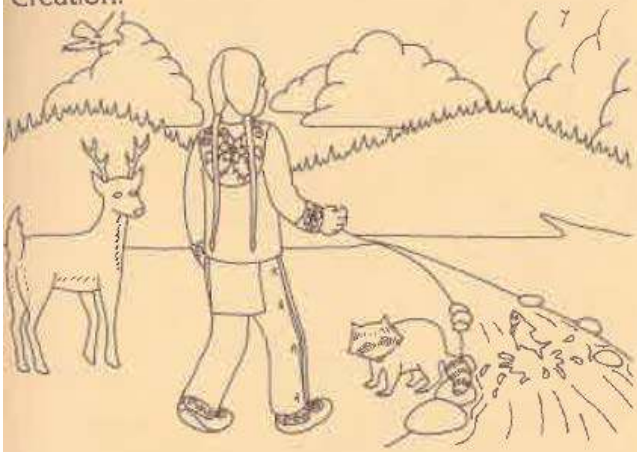
The goal of this Ma'iingan relationship plan is to set a framework of guiding principles for the Bad River Band of Lake Superior Chippewa Indians to understand and coexist with Ma'iingan and to teach others to do the same. In the 2019, the plan was renamed the Ma'iingan *Relationship* Plan. Ma'iingan is a relative and you don't "manage" a relative, you build a relationship with a relative.

Ma'iingan and Anishinaabe told by Mashkiiziibii Elder Joe Rose

"Maybe I should start by talking about the creation. The great spirit came down to the earth, took dust, took it back to the sky world. Breathed life into the dust of Mother Earth, creating Anishinaabe: spontaneous or original man. And then Gichi Manido lowered Anishinaabe to meet his mother. And so the first steps that he ever took was out of love and honor and respect, because the earth was his mother. And so it was the Great Spirit who sent a companion to travel with Anishinaabe: Ma'iingan."

Ma'iingan and Anishinaabe told by Edward Benton-Banai

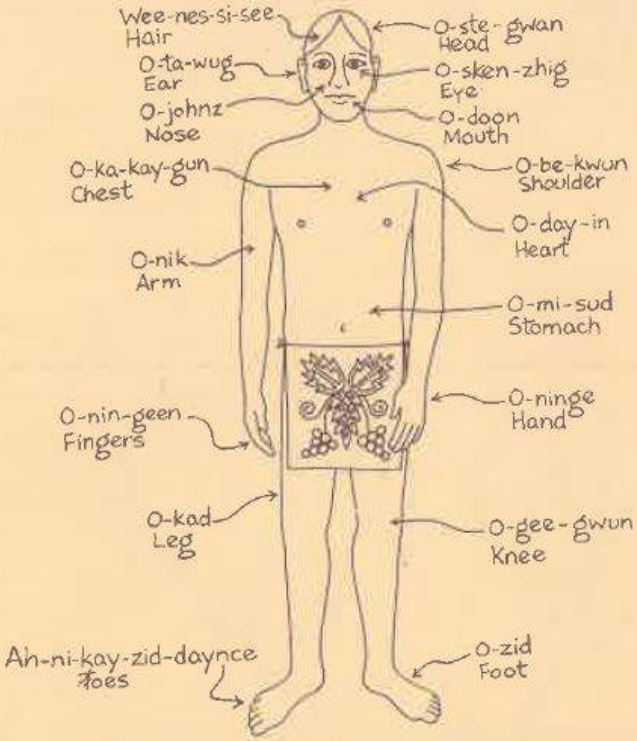
Available online: https://www.upress.umn.edu/book-division/books/the-mishomis-book



Chapter 2

Original Man Walks The Earth

Boozhoo, I have more Ojibway stories to tell you. These e-ki-na-ma'-di-win' (teachings) have been handed down to me by my Grandfathers. In the last chapter we learned of how Original Man was created and lowered to the Earth by the Creator, Gitchie Manito.



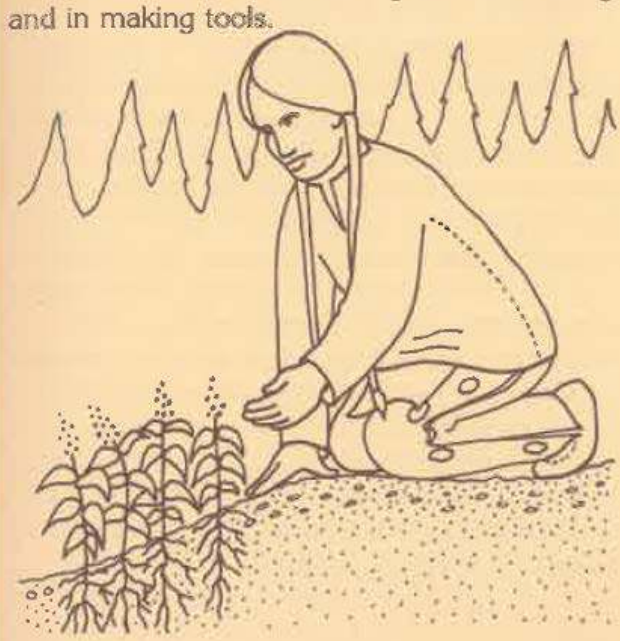
After Original Man was placed on the Earth, he was given instructions by the Creator. He was told to walk this Earth and name all the o-way-se-ug' (animals), the plants, the hills, and the valleys of the Creator's gi-ti-gan' (garden).

Original Man had no name of his own yet. Later, people would refer to him as Anishinabe and, still later, Way-na-boo'-zhoo. But at this early time, he who had no name would name all the Creation.

As Original Man walked the Earth, he named all of the ni-bi' (water). He identified all the rivers, streams, ponds, lakes and oceans. He learned that there were rivers that ran underground. These are the veins of Mother Earth. Water is her life blood. It purifies her and brings food to her.

Original Man also named all the parts of the body. He even named the o-kun-nug' (bones) and organs inside the body.

While Original Man was carrying out the instructions given to him by the Creator, he noticed that the Earth had four seasons. All life was part of a never-ending cycle.



The plants were given new life in the spring. With the coming of summer, they blossomed and bore the seeds for the next generation. Some of the plants produced fruits.

5

In the fall season, the leaves of many of the plants turned from green to many spectacular colors. The leaves gradually fell to the ground as the gee-zhi-gad-doon' (days) got shorter and the dee-bee-kad-doon' (nights) got colder.

In winter, the cold winds of the Gee-way'-din (North) brought the purifying snows that cleansed Mother Earth. Some of the plants died and returned their bodies to their Mother. Other plants fell into a deep sleep and awoke only when Grandfather Sun and the warm winds of the Zha-wa-noong' (South) announced the coming of spring.

As Original Man traveled the Earth, he identified what fruits were good to eat and what was not to be eaten. As he went, he found that some o-gee'-bic-coon' (roots) were good for food. Others were good for mush-kee-ki' (medicine). Some roots could be used to make dyes of different colors and flavorings for food. Other roots could be used as a strong thread in sewing and in making tools.

As he walked, Original Man talked with the animals. He named them as he went. He noted that some animals were good for we-sin'-ni-win' (food) and medicine. He noticed that each type of animal had its own individual kind of wisdom. He did not know what all of these plants and animals would play an important part for all the people that would be coming to live on the Earth at a later time.

Original Man traveled everywhere. There was not one plant, animal, or place that was not touched by him.

In his travels, Original Man began to notice that all the animals came in pairs and they reproduced. And yet, he was alone.

He spoke to his Grandfather the Creator and asked, "Why am I alone? Why are there no other ones like me?"

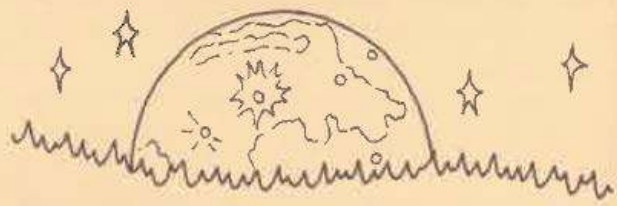
Gitchie Manito answered, "I will send someone to walk, talk and play with you."

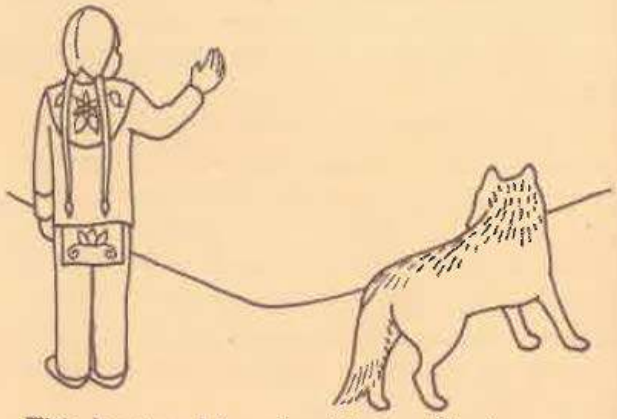
He sent Ma-en'-gun (the wolf).

With Ma-en'-gun by his side, Original Man again spoke to Gitchie Manito, "I have finished what you asked me to do. I have visited and named all the plants, animals, and places of this Earth. What would you now have me to do?"

Gitchie Manito answered Original Man and Ma-en'-gun, "Each of you are to be a brother to the other. Now, both of you are to walk the Earth and visit all its places."

So, Original Man and Ma-en'-gun walked the Earth and came to know all of her. In this journey they became very close to each other. They became like brothers. In their closeness they realized that they were brothers to all of the Creation.





When they had completed the task that Gitchie Manito asked them to do, they talked with the Creator once again.

The Creator said, "From this day on, you are to separate your paths. You must go your different ways.

"What shall happen to one of you will also happen to the other. Each of you will be feared, respected and misunderstood by the people that will later join you on this Earth."

And so Ma-en'-gun and Original Man set off on their different journeys.

This last teaching about the wolf is important for us today. What the Grandfather said to them has come true. Both the Indian and the wolf have come to be alike and have experienced the same thing. Both of them mate for life. Both have a Clan System and a tribe. Both have had their land taken from them. Both have been hunted for their wee-nes'-si-see' (hair). And both have been pushed very close to destruction.

We can tell about our future as Indian people by looking at the wolf. It seems as though the wolf is beginning to come back to this land. Will this prove that Indian people will cease to be the "Vanishing Americans?" Will Indian people emerge to lead the way back to natural living and respect for our Earth Mother?

Background

Coexisting with Ma'iingan is complicated by conflicting relationships that humans have with Ma'iingan. Ma'iingan and Anishinaabe are brothers, but colonization brought a Western mindset of fear and hate toward Ma'iingan to Turtle Island.

Few, if any, Ma'iinganag live their entire life within the boundaries of Mashkiiziibing (Bad River Indian Reservation); because of Ma'iingan's large territory sizes and dispersal characteristics, Ma'iinganag may only spend a short period of their lives within the boundaries of the reservation. In addition, Mashkiiziibing includes not only lands owned by the tribe and tribal members, but also lands owned by private non-tribal individuals and corporations. Contrasting cultural perspectives on Ma'iingan, fragmented ownership of reservation land, and Ma'iingan range sizes underline the complexity of Ma'iingan conservation within and around the reservation and the necessity of coordinating efforts and understanding with the State of Wisconsin.

Introduction

The Mashkiiziibii Tribe is a self-governing entity with which the Federal government relates to on a government-to-government basis. Mashkiiziibii has the sovereignty to develop its own Ma'iingan relationship plan independent of state jurisdiction (Federal Register, 2000).

Mashkiiziibing is located within the Lake Superior Basin and is within the 1842 treaty ceded territory in far northern Wisconsin. The reservation is comprised of 125,000 acres (505 km^2) of land in

Figure 1: Location of the Mashkiiziibing.

Ashland and Iron Counties. Mashkiiziibing is 77% forested, 11% is wetlands and sloughs, and the remainder consists of farmland, residential communities, and roads (Elias, 2001).

Anishinaabeg have a deep spiritual and cultural bond with Ma'iingan. **The purpose of this relationship plan is to foster the lasting presence of Ma'iingan in Mashkiiziibing by supporting coexistence with Ma'iingan.** Due to the research-intensive nature of this plan it is recommended the plan be revisited every five years as new research is made available and as the Mashkiiziibii Reservation continues to change through time.

"Both will be feared, respected, and misunderstood by the people that will later join you on this Earth."

History of Ma'iinganag in Mashkiiziibing and in Wisconsin

Ma'iingan and Anishinaabe

Anishinaabe, the original man, was created to walk the earth and name everything (Benton-Banai, 1988). The Original Man grew lonely and asked the Creator why he was alone. The Creator sent Ma'iingan to Anishinaabe as a companion. They traveled the Earth together as directed by the Creator. Once everything was named, Ma'iingan and Original Man were told they must now travel separate paths, but what would happen to one would happen to the other (Benton-Banai, 1988).

This relationship has held true. Peter David, wildlife biologist for Great Lakes Indian Fish and Wildlife Commission (GLIFWC), outlined the relationship in his writings. He illustrated the correlation between populations of Ma'iinganag rising and of Anishinaabeg gaining recognition of treaty rights (David,2009; figure 2).

Many people today view predators, especially Ma'iinganag, as a competitor for Waawaashkeshii (white-tailed deer). Historically, that was not the case. Ma'iinganag in northern Wisconsin depend on deer for survival and it was traditionally believed that if Ma'iingan tracks were found or Ma'iingan howling was heard in an area that the hunting would be fruitful because these signs indicated that the hunters were in deer country (David, 2009).

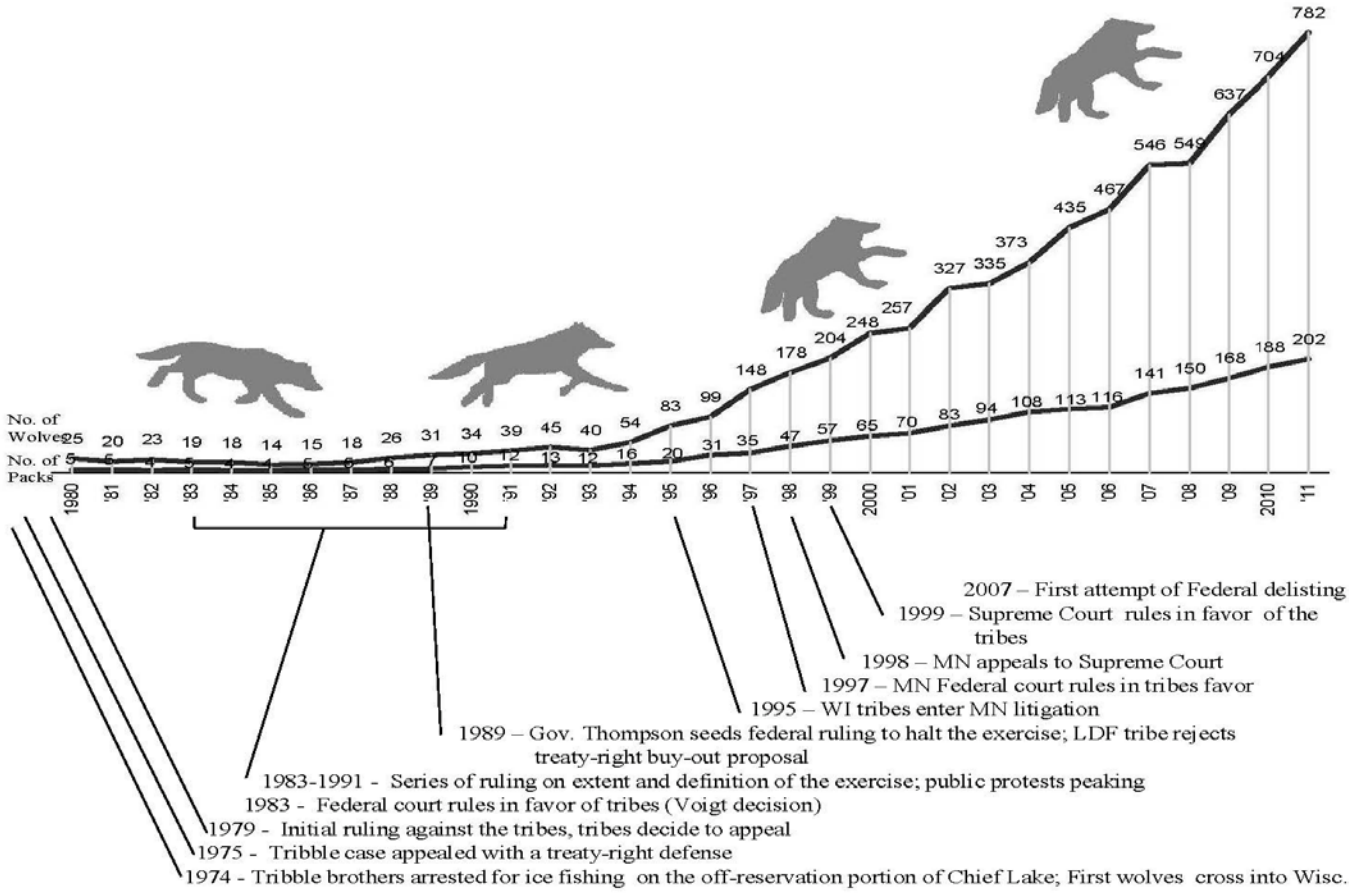


Figure 2: Timeline of battle for Anishinaabe off-reservation treaty rights and the recovery of the Ma'iingan population in Wisconsin provided by Peter David, GLIFWC.

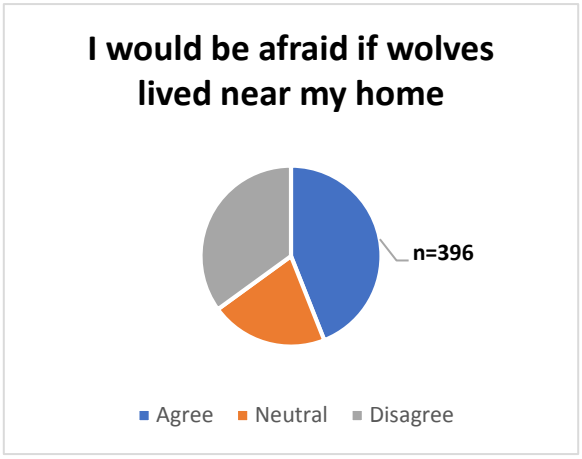
Ma'iingan in Wisconsin

Ma'iinganag were historically present throughout the entire modern State of Wisconsin. Ma'iinganag population estimates for the state ranged from 3,000 to 5,000 individuals before European colonization (Wydeven, 2011). The war against Ma'iinganag in the United States started shortly after Europeans began colonizing the East Coast (Mech and Boitani, 2003). The hatred of Ma'iingan was brought from Europe where humans cleared the habitat of Ma'iingan and Ma'iingan's prey, causing Ma'iinganag to prey on livestock (Linnell and Cretois, 2018). The first Ma'iingan bounty was established in 1630 and by 1700 Ma'iinganag were exterminated from New England (Mech and Boitani, 2003). As colonists moved West, they brought with them their livestock and the war on Ma'iinganag. Mashkode-Bizhiki (American bison; *Bison bison*), Omashkooz (American elk; *Cervus elaphus*), Mooz (Moose; *Alces alces*), Waawaashkeshi (White-tailed deer; *Odocoileus virginianus*), and Adik (Caribou; *Rangifer tarandus*) existed in Wisconsin before European colonization. As Wisconsin was colonized, the land was logged. By 1880, Waawaashkeshiwag were the only large prey species available for Ma'iinganag in Wisconsin (Wydeven, et al. 2009).

The State of Wisconsin first initiated a bounty on Ma'iinganag in 1865 (Thiel, 1993). In 1957, the Wisconsin legislature gave Ma'iingan full protection in the state of Wisconsin (Schanning, 2009). Unfortunately, this was not enough to prevent the last known Ma'iingan in the State from being killed in 1959 (Thiel, 1993). In 1974, Ma'iingan was listed as endangered under the newly adopted federal Endangered Species Act (1973) (USFWS, 1992).

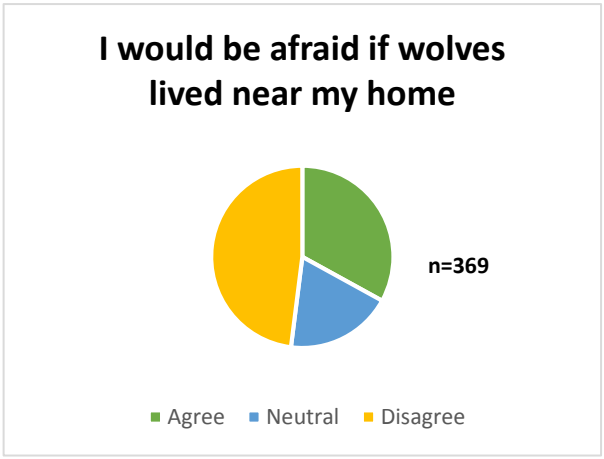
Shortly after federal protections were put into place, Ma'iingan started making a slow comeback in Wisconsin. Ma'iinganag re-entered the state from the remnant Minnesota population. The United States Fish and Wildlife Service (USFWS) developed the 1978 Timber Wolf Recovery Plan, which was last revised in 1992. The Wisconsin Department of Natural Resources (WDNR) began officially monitoring the state's Ma'iingan population in 1979 when there were an estimated 5 packs in the state (WDNR, 1999). A State Recovery Plan

was created by the WDNR in 1989. Wisconsin adopted a State Wolf Management Plan in 1999 (Wydeven et al, 2009).

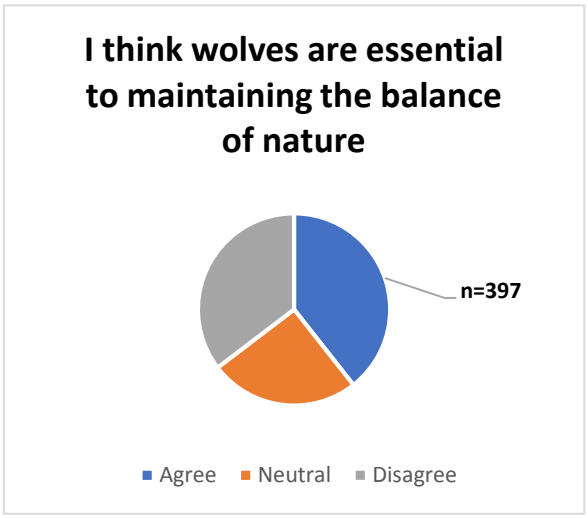


Since the inception of the Endangered Species Act, the listing status of Ma'iingan has changed many times. Ma'iingan have been listed and delisted based in two different regions: Northern Rocky Mountains and Western Great Lakes (Gray Wolf, n.d.). The Service is also involved in the experimental recovery of a sub-species of Ma'iingan, the Mexican Gray Wolf, in New Mexico and Arizona (Mexian Wolf, n.d.). At the time of drafting the 2019 update to the Ma'iingan Relationship Plan, Ma'iingan was delisted in the Northern Rockies and listed as endangered in Wisconsin and Michigan and threatened in Minnesota. The federally listed status of Ma'iingan affects reservation Ma'iingan, because the federal government holds primary conservation responsibility when Ma'iingan is listed as threatened or endangered. When Ma'iingan is delisted, states and tribes hold this sovereignty. Historically, the Service has been sued by groups such as the Humane Association in order to get Ma'iingan re-listed following delistings, because states have not always demonstrated an ability to responsibly conserve Ma'iingan. As of the drafting of this plan revision, the Wisconsin Department of Natural Resources is legally required to hold a harvest of Ma'iingan if Ma'iingan is not federally listed according to Wisconsin State Law, Chapter 29.185 . This law is not scientifically or culturally responsible to Ma'iingan.

As of the 2019 update of the plan, the Fish and Wildlife Service was considering the delisting Ma'iingan across the United States, where they are not already delisted. This proposed delisting received a record number of public comments (1.8 million) and the 5 scientific peer reviews of the proposed delisting largely argued that the population and the Great Lakes States were not ready for the status change (Earthjustice, 2019; Atkins, 2019).



Tribal Views (A Study by Victoria Shelley)



Researchers have been documenting and studying human intolerance of carnivores for many years. Carnivores are often viewed as competition for a food source or as dangerous. In 2009, Victoria Shelley, a graduate student of the Carnivore Coexistence Lab of the University of Wisconsin – Madison, conducted her dissertation research within Mashkiiziibing. Her dissertation was titled, "The Influence of Culture on Attitudes to Wolves and Wolf Policy among Ojibwe Tribal Members and Non-tribal Residents of Wisconsin's Ma'iingan Range" (Shelley, 2011). She completed this study by randomly mailing out questionnaires to Mashkiiziibii Tribal members and randomly selecting non-tribal members that live in Ma'iingan's current range in Northern Wisconsin. A community Ma'iingan Information Meeting was held at the Mashkiiziibii Casino & Convention Center on December 8, 2009 to discuss the study and its results. The study demonstrated that Mashkiiziibii Tribal members were more supportive of protective Ma'iingan policy and less supportive of a proposed Ma'iingan harvest than the non-tribal respondents (figure 3; Shelley, 2011).

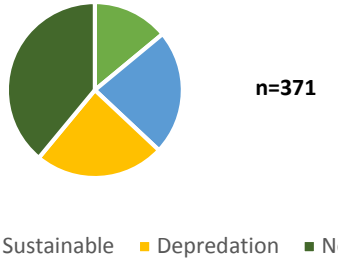
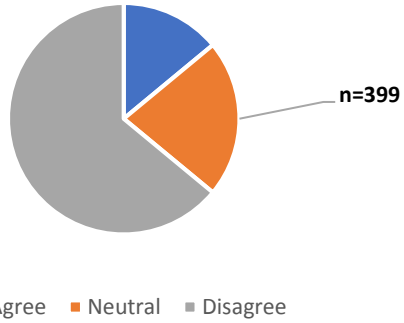
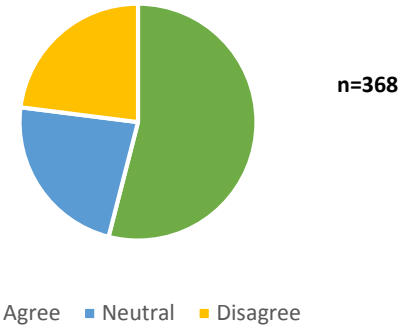
I think Wisconsin's growing wolf population threatens deer hunting opportunities



I think wolves are essential to maintaining the balance of nature

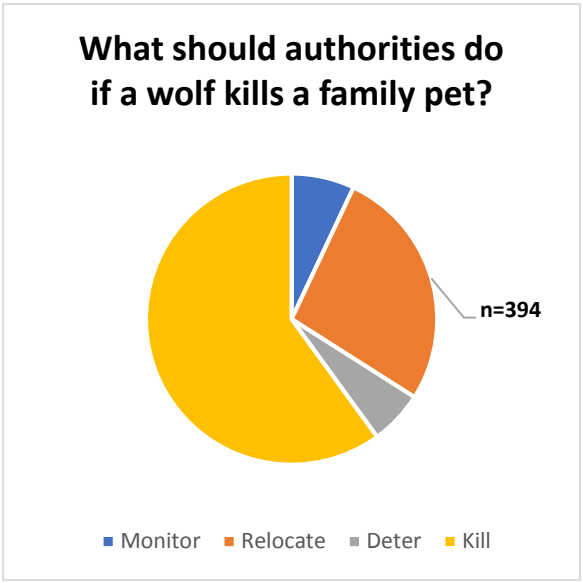


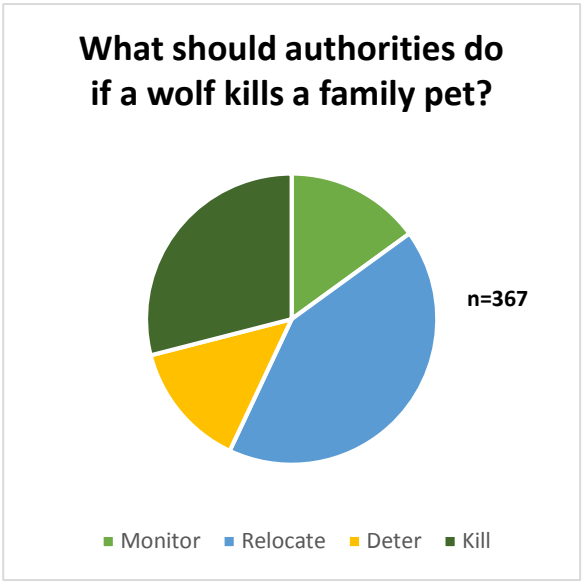
Do you believe there should be public hunting or trapping season on wolves?



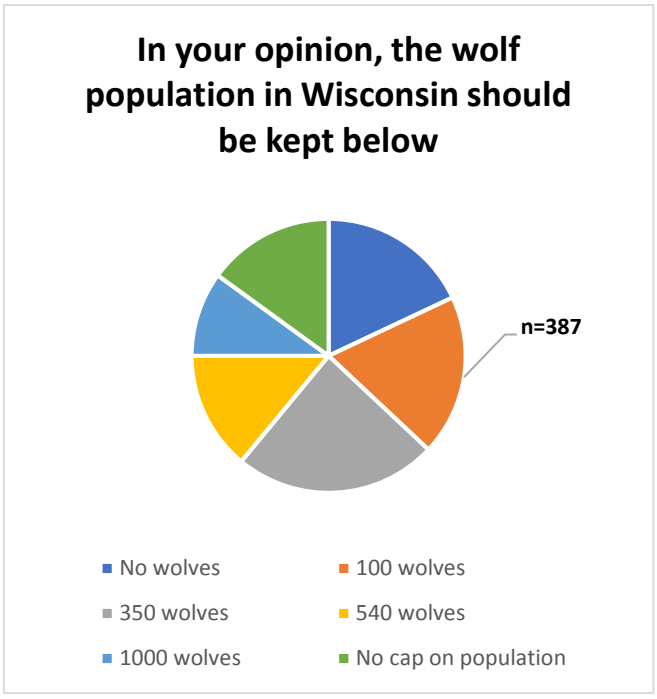
Do you believe there should be public hunting or trapping season on wolves?

Wolves should be protected from hunting and lethal control because of their cultural significance





Wolves should be protected from hunting and lethal control because of their cultural significance



Non Tribal Respondents

Tribal Respondents

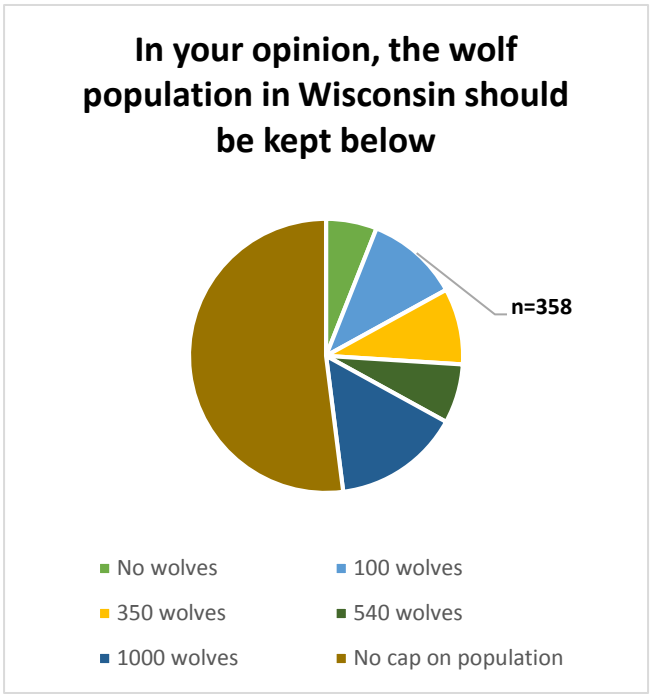


Figure 3: Results from 2009 Victoria Shelley survey of Non Tribal Northwoods residents and Mashkiiziibii Tribal Members

This study showed Mashkiiziibii Tribal members to be more supportive of protective Ma'iingan policy and to have a higher tolerance for Ma'iinganag than non-tribal members (Shelley, 2011). This relationship plan was written to support the strong relationship that Mashkiiziibii tribal members have with Ma'iingan. The Creator told Original Man and Ma'iingan that what happened to one would also happen to the other. Many Mashkiiziibii members believe that the recovery of Ma'iingan and that changing attitudes directly reflect the recovery and treatment of Anishinaabeg.

Livestock Owner, Tribal Member, and Wolf Biologist Views (A Study by Abi Fergus)

A small study of attitudes was also conducted in the summer of 2017 regarding Ma'iingan and the Tribe's Ma'iingan Management Plan. Abi Fergus was a senior at Alma College working as an intern for the Mashkiiziibii Wildlife Program at the time, and sought input from wolf biologists, tribal members, and non-tribal farmers to be considered for the 2019 update of the Ma'iingan Management Plan (Fergus, 2017).

Out of 30 farming operations contacted, three owners gave interviews on their sentiments regarding gray wolves and their conservation. Local wolf biologists were contacted once and all individuals except a representative with the WI DNR responded for an interview. This resulted in four scientists being interviewed. An official count of tribal members offered an interview in person was not kept. Around 1,800 tribal members live on the reservation and every member encountered at the tribal offices and at the daily elder lunch was offered an interview resulting in four members interviewed. A Facebook post detailing the study and providing population information on reservation Ma'iingan was also shared by the former Chief Tribal Warden and the former Tribal Wildlife Specialist as an attempt to gain more interviewees. Many members explained that they felt they were not the right person to speak on Ma'iingan. All but one interviewee had seen a wolf at least once, even if briefly. Most respondents, despite their self-reported attitude, described the event of seeing a wolf as a unique and interesting experience (Fergus, 2017).

Respondents seemed to have the most trouble answering questions relating to how the depredation of pets, livestock, and hunting dogs should be handled. It appeared that interviewees would initially answer

one way if looking at the three categories of animals in an emotional manner and then another way when processing the question with the owner's responsibility to take care of the animal or the owners' financial loss in mind. Costs to government and the historical handling of depredations by government were also discussed in responses by interviewees. Often, the interviewees came to the conclusion that s/he wasn't sure how depredation situations should be handled (Fergus, 2017).

When asked how pet, hunting dog, and livestock owners should protect against wolves killing their animals, answers varied including the following responses (Fergus, 2017):

- Animal owners shouldn't be expected to prevent depredations
- Animal owners can't prevent depredations
- Animal owners should keep animals under control with leashes/fencing
- Animal owners should guard animals with dogs/donkeys/range riders
- Animal owners should use deterrents such as fladry (flagging) and flashing lights
- Animal owners should keep animals near the house, and they should provide a small amount of food for wolves so that they are not tempted by the live animals

In addition to addressing depredations, respondents identified the key aspects of wolf management as being education, communication, wolf monitoring, habitat preservation, effective policy, hands off methods, and understanding the connection between Ma'iingan and Anishinaabeg. A number of wolf scientists, in particular, raised the need to diversify sources of wolf management funding in order to prevent disproportionate control in the issue by a stakeholder group such as hunters, who often pay for conservation via the purchase of hunting tags. Several respondents across stakeholder groups offered applying for grants, fundraising, taxing outdoor hobbyist supplies, collecting donations, finding cheaper management methods, and using funds from special license plates as venues to achieve broader funding (Fergus, 2017).

History of Ma'iingan in Mashkiiziibing

The MWP first began conducting Ma'iingan research within Mashkiiziibing in 1996. The Tribe determined that it was imperative to gain more knowledge on the movements and behavior of Ma'iingan, such as where Ma'iingan dens and rendezvous sites were located, in the face of timber sales, home development, and snowmobile trail establishment on the reservation. In 1996, the MWP determined three Ma'iingan packs spent time within Mashkiiziibing boundaries. These packs became known as the Potato River, West Firelane, and Morrison Creek (or Little's Girls Point Packs in Michigan). Later on, the Kakagon Sloughs pack was also identified within the reservation (Doolittle, 2001).

Figure 4: Photograph of tracking Ma'iinganag using radio telemetry from an airplane, provided by Lacey Hill-Kastern.

Since 1999, MWP has put radio collars on 10 Ma'iingan in order to learn about their habitat use, denning and rendezvous patterns, mortality causes, total population, and pack distribution on the reservation. In 2019, the Wildlife Program put an indefinite moratorium on collaring Ma'iingan, unless it can clearly be determined that collaring Ma'iingan will have direct benefits for Ma'iingan that outweigh the burden and risks that VHF and GPS collars pose. The MWP continues its historical use of howl surveys and track surveys to understand reservation Ma'iingan.

Ma'iingan Biology and Ecology

Description

At first glance, some may mistake a large Ma'iingan for a large Animosh (domestic dog; *Canis lupus familiaris*). Ma'iinganag are the largest members of Canidae (dog family), in North America. They can stand 26 to 38 inches (66 to 96 cm) high at the shoulder, with a body length of 40 to 58 inches (101 to 147 cm) long, and weight of 60 to 100 pounds (27 to 45 kg) (Busch, 1995). Ma'iinganag differ from Animoshag in several ways. Ma'iingan differs from a domestic dog in that it has longer legs, larger feet, a narrower chest, a straight tail, and tufts of hair on the sides of his or her face extending from below the ear (Paquet and Carbyn, 2003).

Other members of the dog family that are found in Mashkiiziibing include Wiisagi-Ma'iingan (coyote; *Canis latrans), Waagosh* (red fox; *Vulpes vulpes*), and the gray fox (*Urocyon cinereoaryenteus*). Ma'iinganag are much larger than any of these species. Wiisagi-Ma'iingan has a narrower face and pointier ears than Ma'iingan. Ma'iinganag may be mistaken for Waawaashkeshi due to their long legs. Ma'iingan's eyes are golden brown, and when you shine the eyes at night, they appear greenish-orange in color and appear closer together than Waawaashkeshki eyes do (Busch, 1995).

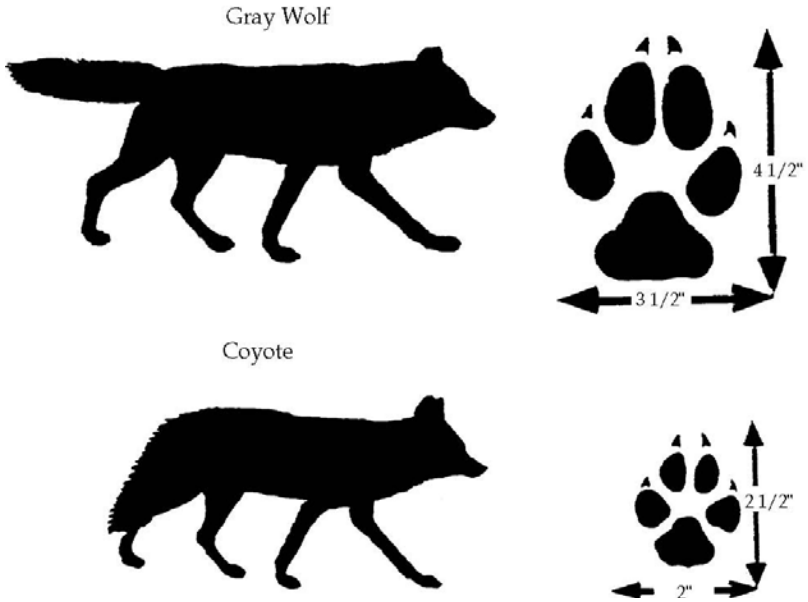

Figure 5: Ma'iingan and Wiisagi-Ma'iingan silhouettes and tracks (Paul and Gibson, 1994).

Ma'iinganag can be various shades of gray, tan, brown, white, and even all black. Each of these colorations have been observed and documented among the various packs on the reservation. Black Ma'iinganag are more common in the northern part of their range and can comprise up to one-third of the northern Ma'iingan population (Busch, 1995).

Track and Scat Identification

Ma'iingan tracks looks similar to those of Animosh. Each track consists of a pad, four toe prints, and 4 indentations above the toe pads (marks left by claws). Ma'iingan's track size is typically 4.5 to 5.5 inches (11 to 14 cm) in length and 3.5 to 5 inches (8 to 12.5 cm) in width, which is an unmistakably large paw print (Forrest, 1988). The print of Wiisagi-Ma'iingan is substantially smaller, typically 2.5 to 3.5 inches (6 to 9 cm) in length and 2 to 2.8 inches (5 to 7 cm) in width (Forrest, 1988) (Fig 5). Some Animosh breeds can leave a track similar in size to Ma'iingan. Animosh's toes point slightly outward, whereas Ma'iinganag toes will point straight ahead (Busch, 1995). Ma'iinganag also have more direct paths of travel and their tracks will often appear in a straight line versus Animosh, which will tend to wander.

Ma'iingan scat may appear similar to that of Animosh in size, but Ma'iingan scat is mostly comprised of hair and bone fragments. The feces are 0.5 to 6 inches (1 to 15.25 cm) in length and 1 to 1.5 inches (2.5 to 4 cm) in diameter and have tapering ends (Busch, 1995; Forrest, 1988). Wiisagi-Ma'iingan scat may appear similar, but is rarely over 4 inches (7.6 cm) in length or 1 inch (2.5 cm) in diameter (Forrest, 1988) (Fig 6).

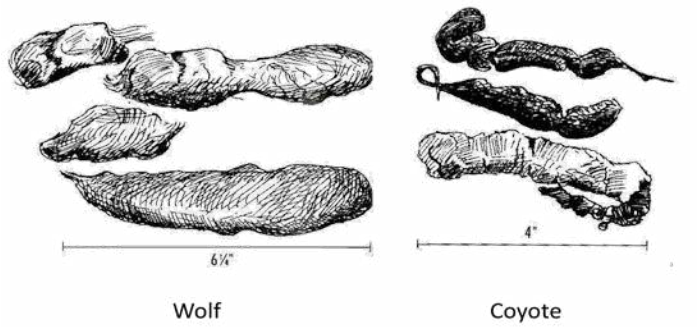

Figure 6: Ma'iingan vs Wiisagi-Ma'iingan scat (Paul and Gibson, 1994)

Mashkiiziibii's first Wildlife Specialist, Tom Doolittle, gathered habitat use data from the first three Ma'iingan to be collared and tracked on the reservation in the late 90s and early 2000s. Pack structures on the

reservation have changed since his writing, but Doolittle offers insight into reservation Ma'iingan's tie to waterways.

> "Regardless of the agency gathering relocation data from the air, all but four of 46 points were within riparian zones as defined by the IRMP set of buffers. Reservation GIS vegetation data also supports use within 200m of wetland types. Home ranges included 90% of the described vegetation types on the reservation. Sixty percent of air observations of wolves on the ground had a coniferous component in their respective habitat. Wolves avoided agricultural areas, main State highways and entered the reservation in the southeast quadrant of the reservation." (Doolittle, 2001).

Ma'iinganag are considered to be "habitat generalists" and can survive in a variety of habitat types, dependent on prey availability (Gehring and Potter, 2005; Mladenoff et al., 1999). Ma'iinganag require large tracts of land with adequate prey populations. Ma'iingan's diet has not been studied in Wisconsin since the 1980s, when Ma'iingan was first returning to Wisconsin after being extirpated. At the time of the master's dissertation study, Ma'iingan was found to be primarily eating Waawaashkeshiwag and secondarily preying on Amik (American beaver; *Castor canadensis*) with some Waabooz (snowshoe hare; *Lepus americanus*) in the diet (Mandernack, 1983). Ma'iingan's population and habits in the ceded territory have changed since this diet study, and it is a goal of the Mashkiiziibii Wildlife Program to study the diet of reservation Ma'iinganag. In more modern studies that took place elsewhere in North America, Ma'iinganag have been known to supplement their diet with rodents, birds, eggs, fish, berries, carrion, and other carnivores such as bears and river otters (Paquet and Carbyn, 2003; Chavez and Gese, 2006; Gable et al., 2019; Gable et al, 2018). A study out of Voyageurs National Park in Minnesota found that one Ma'iingan pack ate 38-42 percent of Amikwag within the pack's home range (Gable and Windels, 2017).

Ma'iinganag, as apex predators, can influence more evenly dispersed grazing by ungulates (Ripple and Beschta, 2012). Not only does this have the potential effect of preventing all individuals of a plant species from

existing only in disease-susceptible clusters, but it also can establish critical habitat. The even spread of ungulate browsing due to predation pressure from wolves may bring other benefits. For example, the woody plants that have been found to grow more successfully after wolves reoccupied Yellowstone provide shade over rivers, which cools water. This phenomenon supports cold water fish such as trout (Wilmers et al., 2012). This theory of how wolves shape an ecosystem, called top-down trophic cascades, needs to be further researched in geographical locations outside of Yellowstone, but it is an influence that various large predators around the world seem to have on their respective ecosystems (Dyer and Letourneau, 2002; Pace et al, 1999; Ripple and Beschta, 2012).

Despite the common belief that wolves are competing with people for venison, they can be beneficial for prey populations (Burt, 1952; DelGiudice, 2010; Wilmers et al., 2012). Wolves cull the old, sick, and very young from the herd, which can stimulate productivity by freeing more food and cover to support a healthy population of deer (Kurta, 1995). Various studies have shown conditions in which wolves act as compensatory predators, killing prey that would have otherwise died from causes such as disease or age (Griffin et al., 2011; Sand et al., 2012; Wright et al., 2010). Humans don't usually hunt in this way. Waawaashkeshi fawns are important prey for Ma'iinganag in the summer. Research conducted in Minnesota found that nine fawns are eaten per adult Ma'iingan and each Ma'iingan has an estimated kill rate of eighteen Waawaashkeshiwag per year (DelGiudice, 2010). However, the kill rate is not universal and is dependent on location, winter severity, and a number of other factors (DelGiudice,2010; Metz et al., 2012). Ma'iinganag are not efficient hunters of Waawaashkeshi and studies have shown that most hunts are brief and unsuccessful (Stark, 2009).

Chronic Wasting Disease (CWD) and Ma'iingan

Ma'iingan may play a part in controlling disease within prey species. One example is chronic wasting disease (CWD), an illness that degrades the brains of cervids (deer species) and leads to certain mortality (Geist et al., 2017). CWD has been a growing issue for Cervidae, such as Waawaashkeshiwag and

Omashkoozwag in North America. Similar to mad cow disease, CWD is understood to be caused by the misfolding of a protein (called a prion) and can be transferred directly between infected individuals and indirectly from contaminated habitat where the individual browsed, defecated, or died. This prion disease is classified as transmissible spongiform encephalopathy (TSE), which means it can be spread between individuals and causes holes in the nervous tissue. The contagions can then remain in the environment for years. Human hunting of contaminated cervids is not as likely to reduce the prevalence or spread of CWD as Ma'iingan predation is, because humans cannot visually detect a CWD-infected deer unless it is in the late clinical stages of the disease. Humans are not likely to control CWD because we tend to harvest the healthiest individuals rather than the young, old, or sick individuals. Current trends in CWD prevalence seem to be unaffected by human hunting practices once the disease has become established on the landscape. The disease is contagious before its symptoms in infected animals are apparent to humans. Within weeks of infection, a cervid individual may become contagious, but signs of clinical-stage infection visible to humans do not manifest until 6 to 11 months after the initial infection. The disease takes 18 to 36 months to run its course, ending with the death of the cervid (Wild et al., 2011).

Ma'iinganag may be able to pick up on CWD disease cues earlier than humans, because prey individuals that carry disease or parasites often are conspicuous to non-human predators. If Ma'iingnag were to selectively prey on Waawaashkeshiwag with CWD, this could contribute to a more stable cervid population. This is because mortality would be more consistent if caused largely by predation rather than by disease. Even if Ma'iinganag do not actually have the capability of early disease detection, Ma'iingan predation on cervid populations might CWD in check by reducing population density and thus the spread of disease. Predation behavior research, however, indicates that Ma'iinganag prefer preying on young, old, and diseased individuals and this indicates that they may be capable of detecting CWD. Canines seem to break down the CWD prion within the digestive tract rather than take up the disease or continue its spread (Wild et al., 2011).

One model projects Ma'iingan, rather than humans, having a superior ability to suppress the disease within a population of cervids. This is based on the condition that Ma'iinganag remove 15 percent of the deer

population per year. This study was by no means perfect. Future research should model the risk of CWD spread from cervid carcasses, in addition to live Waawaashkeshiwag, as an indicator for the prevalence of the disease in an environment (Wild et al., 2011). In another study that took place in Spain, cattle and wild boar within Ma'iingan range were found to have less prevalence of tuberculosis (Tanner et al., 2019). Modeling showed that if Ma'iingan populations remained stable, that tuberculosis would remain controlled, but if the Ma'iingan population crashed the disease would rebound (Tanner et al., 2019).

In a closed population of Omashkooz (American elk; *Cervus elaphus*) within Rocky Mountains National Park (which is comparable in size to the Bad River Reservation), one researcher's modelingg showed that wolves could eradicate CWD in elk within 19 years (Hobbs, 2016). Omashkoozwag seem to have a slower transmission rate than Waawaashkeshkiwag and CWD seems to transfer more through indirect means such as scat (Hobbs, 2016). Still, this study is helpful to consider as Mashkiiziibii Wildlife Program has a goal to return Omashkoozwag to Mashkiiziibing, and their relationship to CWD is an important consideration. The restoration of Omashkoozwag to Mashkiiziibing may even cause a more dispersed Waawaashkeshiwag population on the reservation, and thus reduce the potential for direct transmission between Waawaashkeshkiwag.

The latest estimate of Ma'iingan predation on Waawaashkeshkiwag was done by the WI DNR in 2009 (WDNR, 2009). This study found that Ma'iingan was only preying on about 1.3% of the Waawaashkeshiwag population when the Ma'iingan population in the state was estimated by the WI DNR to be about 626-662 individuals (WDNR, 2009). Though the Ma'iingan population in 2018 was estimated to be about 905-944 individuals, this population would still not reach 15 percent predation on the 2019 estimate of 1.8 million Waawaashkeshiwag in Wisconsin (WDNR, 2009; WDNR, 2019).

Causes of Ma'iingan Mortality

In a given year, approximately 70% of Ma'iingan pups die, while deaths among Ma'iinganag one year or older averages 25% of the population segment (Wydeven et al. 2012). According to Wisconsin's 2018 Year

End Ma'iingan Population Monitoring Summary, 36 adult Ma'iinganag were found dead in the state during the year, 4% of the year end count population of 925-952 Ma'iinganag. Of the 36 dead Ma'iinganag: 39% were killed by vehicles and 19% were illegally shot. Humans caused 72% of 2018's Ma'iingan mortality. More disease caused deaths occurred in 2018 than in the previous two years, with 16% of deaths attributed to disease out of 28% of deaths being attributed to natural causes as a whole (Wiedenhoeft, 2018).

Ma'iinganag are susceptible to many diseases and parasites. Canine distemper, canine parvovirus, lyme disease, and blastomycosis have all been documented in Ma'iinganag in Wisconsin (WDNR, 1999). Sarcoptic mange has also been frequently observed on Ma'iinganag and has been documented in Mashkiiziibing (Jimenez, 2010; Doolittle, 2001). Ma'iinganag are also susceptible to external parasites such as flies, ticks, fleas, mosquitoes, and mites. Historically in Wisconsin, humans are the number one cause of Ma'iingan death via poaching and car accidents (Treves et al., 2019).

Ma'iingan Behavior and Social Structure

Ma'iinganag are social animals and live in family units known as "packs." By definition, a pack always consists of at least a breeding pair (formerly known as an alpha pair). Pack size changes on an annual basis and most often consists of the pups produced that year, the previous year's surviving offspring, and sometimes older offspring that have not dispersed or an unrelated adult that was accepted into the pack. The average ma'iingan pack in Wisconsin has 3 to 4

Figure 7: Gimiwan (it rains), a breeding male reservation ma'iingan, provided by Abi Fergus

members, not including pups (Paquet and Carbyn, 2003).

Ma'iinganag typically mate from January to April. A female is in estrus for five to seven days (Paquet and Carbyn, 2003). Ma'iinganag can become breeders between one to three years of age, but not all will breed. Often, 2-3 year old Ma'iinganag disperse from their packs in order to find breeding opportunities. Ma'iingan can find a mate in a new territory or form its own pack. Ma'iingan can be accepted into a pack and wait for a breeding opportunity, or it can oust a pack breeder and take over that position (Mech, 2003).

Definition:
Tribally Protected Species – *Any species that may or may not exist on the Mashkiiziibii Reservation, that the Mashkiiziibii Tribal Council and Mashkiiziibii Wildlife Program determine needs additional protections against hunting and other harms.*

Pups are born from early April to early June after a 62-63 day gestation period (Paquet and Carbyn, 2003). Litter sizes vary from one to eight pups, with an average litter size being six (Paquet and Carbyn, 2003). At four weeks old, pups will begin to leave the den; pups are able to travel

up to a mile from the den at five weeks old (Busch, 1995). Pups are moved to a "rendezvous site" once they are physically able to make the journey. A rendezvous site is an area where the pups stay while the rest of the pack hunts; it can also be referred to as a summer "nursery" site. One pack may have several rendezvous sites in its territory. At 3 months, pups will accompany adults on hunts; by seven to eight months pups actively hunt as a member of the pack (Busch, 2005).

Mashkiiziibii Ma'iingan Relationship Policy

Prior to the Ma'iingan Relationship Plan, the Tribe's Ma'iingan relationship policy had been to follow federal policy and to work cooperatively with the state, USFWS, and GLIFWC. After being delisted, Ma'iinganag were classified as a "*tribally protected species*" by the Mashkiiziibii Tribal Council. This classification, along with the Ma'iingan Relationship Plan, will be revisited every 5 years by the Mashkiiziibii

Tribal Council and MWP. Classification can be revisited sooner if deemed an emergency by Tribal Council and MWP.

MWP will honor the relationship between Ma'iingan and Anishinaabeg. MWP will not work towards a specific Ma'iingan population in and around Mashkiiziibing, but instead will work to ensure the long-term presence of Ma'iingan by supporting coexistence. MWP will work for a minimum ma'iingan population goal of three packs in Mashkiiziibing, as there historically have been three year round packs and one seasonal pack on the reservation. Non-lethal tactics, such as guard animals and deterrent devices, will be used to respond to and prevent conflict between Ma'iingan and domesticated animals. Under this plan, the only legal killing of Ma'iinganag will occur in circumstances where non-lethal methods have not worked or are not deemed feasible by MNRD staff to protect domesticated animals.

MWP will continue to use both traditional ecological knowledge and western science in monitoring the Ma'iingan population in Mashkiiziibing. The tribe will also continue to work with tribal, state, and federal agencies as well as with private landowners to ensure the sustainability of Ma'iinganag in Mashkiiziibing, in the state of Wisconsin, and in the Great Lakes Region.

If the Population Falls Below the Minimum Goal

MWP will not set a population cap on the Ma'iingan population in Mashkiiziibing or in the buffer zone. Since 1996, Mashkiiziibii Wildlife Program has monitored three to four Ma'iingan packs utilizing the lands within the reservation. Mashkiiziibii Wildlife Program has set a minimum population goal of at least three packs partially occupying the reservation.

If the population falls below this goal, immediate consultation will occur with the United States Fish & Wildlife Services and the WI DNR. Monitoring efforts and a possible reason for the population decline will be evaluated by MWP. MWP will seek to identify any major habitat changes, prey population declines, and/or possible disease outbreaks. The status of Ma'iingan outside of the reservation will also be evaluated.

Traditional Ecological Knowledge

> "In order to be involved with wolf conservation, the State and Federal government need to understand how to take care of wolves. That's what the Anishinaabe have done for years by observing and learning. Conservation of wolves is a part of our history. If we allow them to be killed, we allow ourselves to be killed." – Edith Leoso, 2017

This statement by Tribal Elder and Historic Preservation Officer Edith Leoso underlines the importance of Traditional Ecological Knowledge (TEK). TEK is passed down through generations of indigenous peoples (Service et al., 2014). This knowledge is formed over long periods of time in which an indigenous nation lives on a landscape (Adams et al., 2014). Anishinaabeg are believed to have finished the great migration to Mooninwaane'akaaning Minis (known as Madeline Island in English) around 1400 (About Anish:Timeline), but had shared the landscape of modern North America with Ma'iingan for more than 8,000 years (Our Proud History).

Generally, indigenous peoples of North America lived in a sustainable manner before colonization occurred and influenced this way of life (Wood and Wilckers, 2008). Hunter-gatherer lifestyles gave indigenous peoples an intimate knowledge of their dependency on other life, from predators to prey (Wood and Wilckers, 2008). Anishinaabeg have learned skills and morals from Awesiinhyag (animals) and animal Manidoog (spirits) (Benton-Banai, 1988). Anishinaabeg hold a wealth of knowledge in coexisting with Ma'iingan held by tribal members and in traditional stories.

In addition to the Anishinaabe creation story involving Ma'iingan, various other stories involve Ma'iingan teaching lessons to Anishinaabeg (Usik, 2015). These stories often reflect what environmental values Anishinaabeg have traditionally held. The analysis of these stories and the lessons Anishinaabeg gain from them may also help to shed light on how they successfully co-inhabited North America with Ma'iingan. One Anishinaabe value these stories exemplify is that humans are lesser than other members of their ecosystem, because of the dependence humans have on other biota to survive. This contrasts with Western attitudes of dominance over the natural world, which much the scientific community is influenced by.

The wildlife program will pursue TEK on Ma'iingan, value it along with the scientific method, and incorporate it into its conservation work. Thus far, this knowledge has been pursued at elder lunches, community events, and a conversation circle leading up to the 2018 update of the Ma'iingan Management plan. The wildlife program will accept knowledge that may help inform Ma'iingan conservation at any time. Adams et al. (2014) outlines a framework we can use to form research questions based on TEK while using the scientific method so that those who have not yet accepted TEK for its inherent value may accept the same knowledge in the form of scientific results.

Mashkiiziibii's Policy on the Harvest of Ma'iinganag

To Anishinaabeg, the loss of one Ma'iingan is equal to that of a loss of a brother/sister. All ma'iinganag are sacred to Anishinaabeg, therefore the Mashkiiziibii Tribe does not support the killing of Ma'iinganag, but does understand the importance of protecting one's animal companions.

At the Mashkiiziibii Tribal Council meeting on May 9th, 2012, the Tribal Council and the community members present spoke out against the sport killing of Ma'iinganag. At that meeting, the Mashkiiziibii Tribal Council approved an emergency rule prohibiting the harvest of Ma'iinganag within the exterior boundaries of Mashkiiziibing. The Bad River Band of Lake Superior Chippewa Indians is opposed to the recent State of Wisconsin Ma'iingan hunts and the interpretation of the 350 Ma'iingan population number in the Wisconsin Wolf Management Plan as being an upper limit on Ma'iingan's population (Appendix A). The Mashkiiziibii Tribe knows that there should be no population cap placed on Ma'iingan and that the State should focus on supporting coexistence with Ma'iingan.

Mashkiiziibii Wildlife Program Responsibilities

The Mashkiiziibii Wildlife Specialist will be responsible for the implementation of this plan. The Wildlife Specialist, with the assistance of Tribal Wardens, will also be responsible for co-investigations conducted within the buffer area surrounding the reservation, depredation investigations within the exterior

boundaries of the reservation, the coordination of inter-agency monitoring and conservation activities, and the annual recording of the reservation Ma'iingan population.

The Wildlife Specialist will also be responsible for participating in any state, federal, tribal and regional meetings regarding Ma'iingan. Summaries of these meeting will be kept on file at the MNRD office and updates will be provided to the MNRD Department Director on an annual basis. MWP will continue to provide comments on proposed state and federal Ma'iingan conservation strategies and documents. Routine coordination will occur with federal, state, and surrounding land managers to ensure proper protections for Ma'iinganag are taking place to ensure protection of the local population.

Regulations under this Ma'iingan Relationship Plan will be enforced by Mashkiiziibii Tribal Wardens and necessary coordination with federal, state, and local authorities will occur under the guidelines of this plan.

What makes a Ma'iingan a "Reservation Ma'iingan?"

During the delisting process and the introduction of Wisconsin Act 169 2011, the term "reservation wolf" or "reservation pack" was commonly used. MWP defines a reservation Ma'iingan as a Ma'iingan or pack whose home range is found, at least in part, within the exterior boundaries of Mashkiiziibing. This information has been confirmed by radio collar locations and combined tracking efforts between MNRD and WDNR. These packs shall be protected when they travel off-reservation as well as when they remain on reservation.

Conservation Responsibility in the Buffer Zone

Mashkiiziibii has sovereignty over the reservation and holds rights to hunt, fish, and gather in the ceded territory, which makes up roughly the northern third of modern-day Wisconsin. Ma'iingan does not recognize human political boundaries. Mashkiiziibii Ma'iingan research dating back to 1996 shows that reservation wolves regularly travel off reservation. The following map of a collared Ma'iingan demonstrates how reservation Ma'iinganag travel throughout the six mile buffer of Mashkiiziibing.

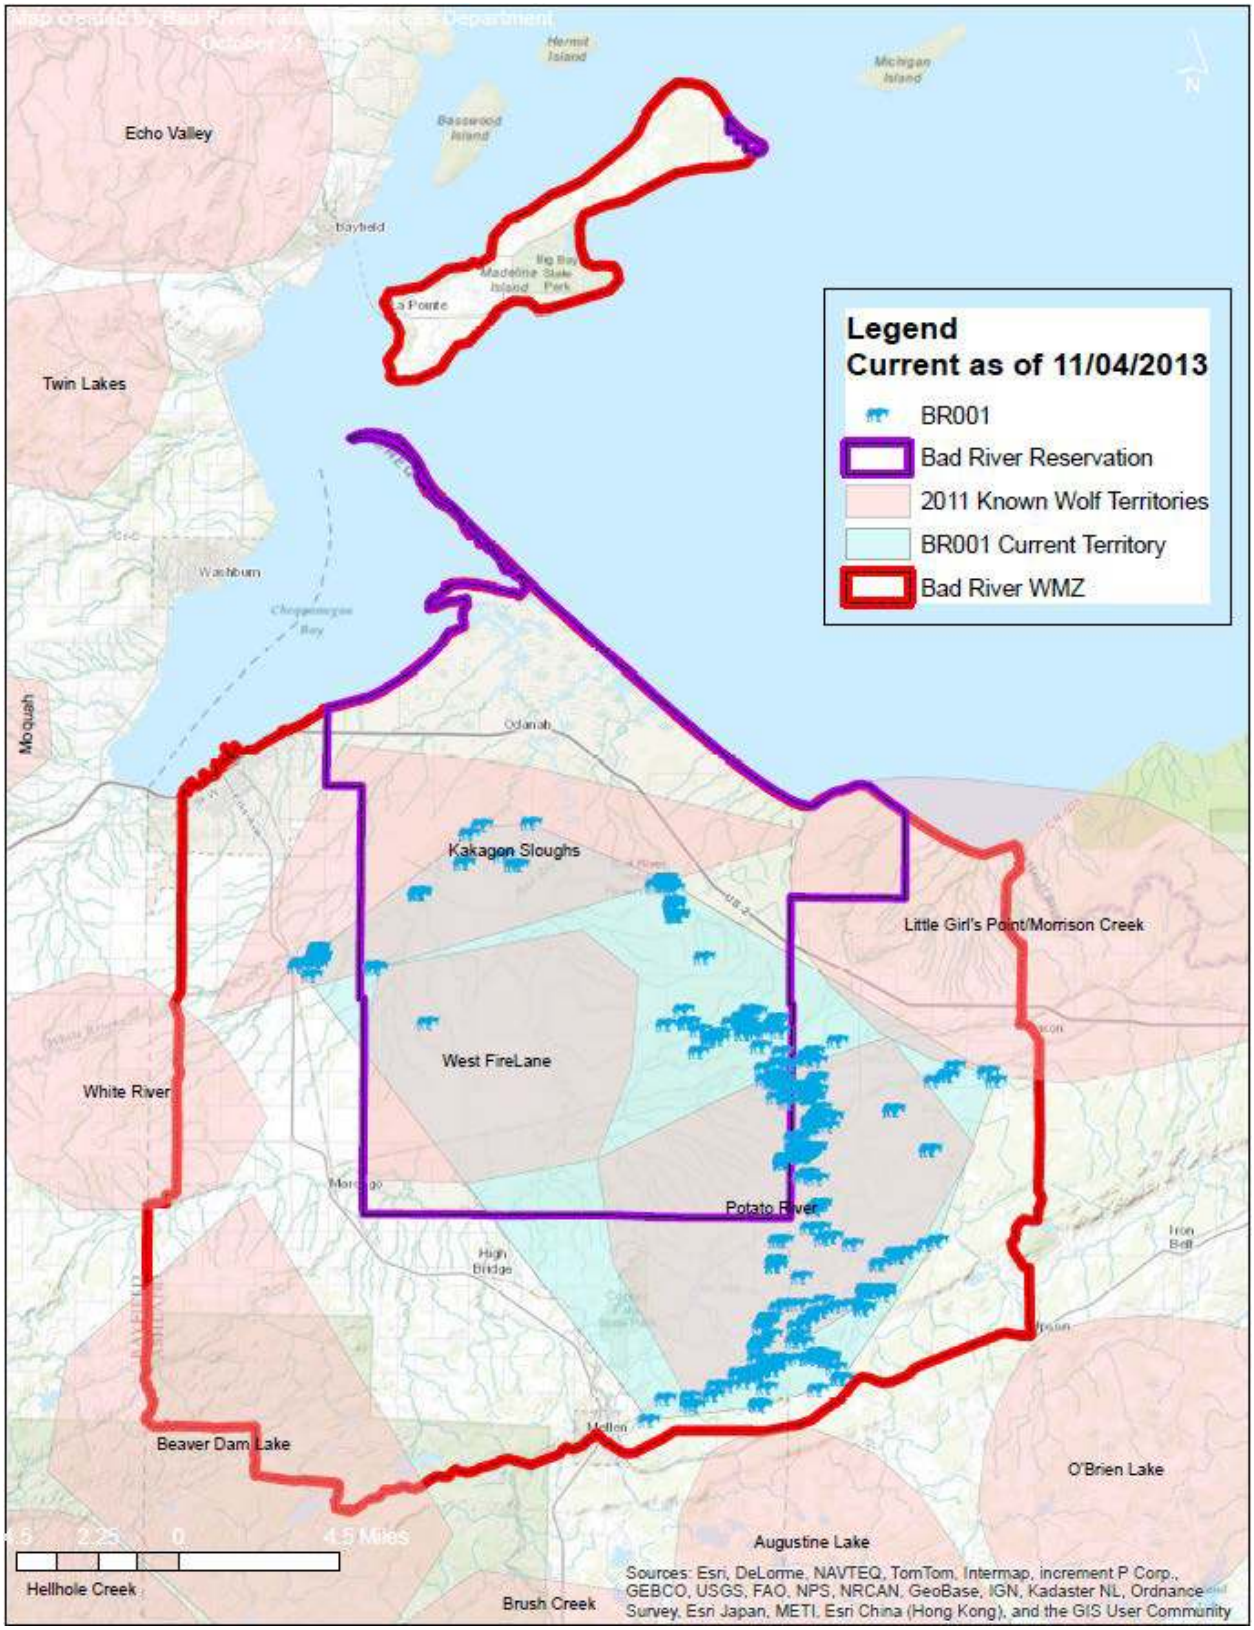

Figure 8: Movement of a formerly radio collared ma'iingan on the Mashkiiziibii reservation

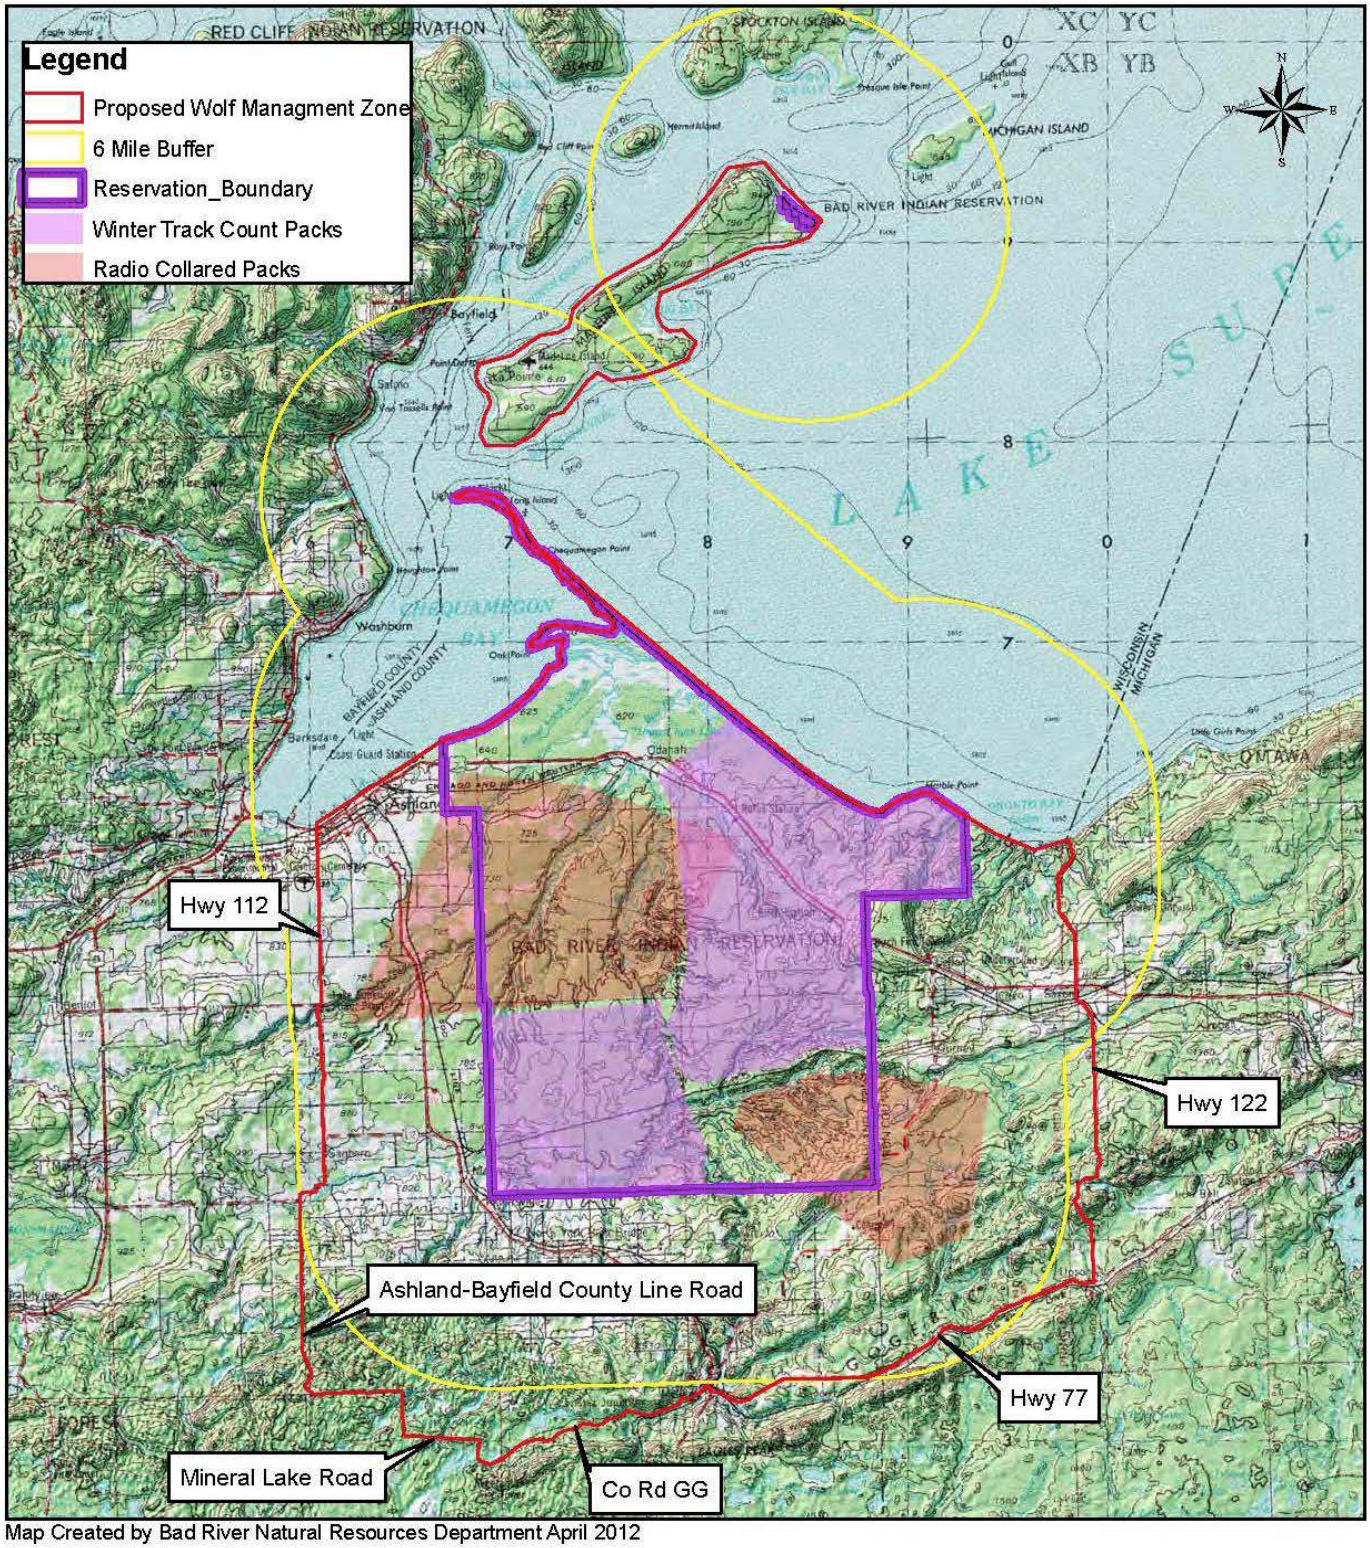

For Mashkiiziibii's sovereignty to be honored, extended protections for reservation Ma'iingan must be recognized by the state. Mashkiiziibii has been advocating to the State of Wisconsin for the protection of reservation wolves, which also travel off reservation, at least since the early 2000s (when Ma'iingan was temporarily federally delisted) (Doolittle, 2001).

In the State of Wisconsin, the WDNR, APHIS-WS, and tribes with large reservations have been working cooperatively on reservations, within a six mile buffer of the reservations, and within the ceded territories. If there is a conflict between people and Ma'iinganag within six miles of a reservation (Bad River, Red Cliff, Lac Courte Oreilles, Lac Du Flambeau, Menominee, Stockbridge-Munsee), tribal representatives are to be notified and to be given the opportunity to investigate the scene with APHIS-WS professionals. At an investigation, a reactive depredation control method is discussed with all parties including the landowner.

The Mashkiiziibii Ma'iingan Relationship Plan extends beyond the reservation's boundaries, encompassing six miles around the reservation's borders (Figure 9). The buffer zone boundary runs along easily distinguishable roads to reduce possible confusion. The unit runs from Chequamegon Bay along Hwy 112, to Ashland-Bayfield County Line Road, to Mineral Lake Road, to Co Rd GG, to Hwy 77, then back along Hwy 122, and ends at the Wisconsin-Michigan border. A portion of Mashkiiziibing is located on Mooninwaane'akaaning Minis (Madeline Island). Ma'iingan is not currently known to live on Mooninwaane'akaaning Minis, but Ma'iingan has been document on Stockton Island (the largest of the Apostle Islands) and the buffer zone extends around the reservation land on Mooninwaane'akaaning Minis (Allen et al., 2016). Within this zone, there shall be a zero quota for public harvest. The Tribe does recognize the importance of private landowners and their need to protect their domesticated animals. Therefore, the tribe is understanding of the issuance of an individual landowner permit to kill Ma'iingan **as a last resort**, as long as the following circumstances apply:

- Domesticated animal depredations have occurred within the last six months and there was tribal representation on the investigation
- Other non-lethal abatement methods were tried and documented but found unsuccessful
- Multiple domesticated animal damages (adverse health effects or death resulting from a verified ma'iingan attack) have occurred and have been verified to have been caused by ma'iingan by co-investigations with tribal staff
- After co-investigations with APHIS-WS and MNRD, it has been determined that lethal methods are appropriate

MWP understands that there are diverse, non-lethal tactics to coexist with Ma'iingan and which are ethically, scientifically, and culturally better options than lethal action. The Mashkiiziibii Wildlife Specialist needs to be involved in depredation investigations within the buffer zone. Because of the small number of Ma'iinganag associated with Mashkiiziibing and their frequent use of both on and off-reservation lands, the impact of depredation control is significant.

Map Created by Bad River Natural Resources Department April 2012

*Red polygons are Minimum Convex Polygons created from location data collected on radio collared individual by the WDNR.
Purple polygons are packs known to exist from winter track counts, observations, and other infomation collected by staff.
More data needs to be collected outside of the exterior boundary of the reservation to complete polygons.

1 in = 5 miles

Figure 9: Map of buffer zone and reservation packs

Ma'iingan and Livestock

In the most recent 5 year report from the USDA on cattle mortality, a historic trend continued in which predators accounted only for a small percentage of cattle deaths (Figure 10; USDA, 2017).

Figure 10: USDA data on cause of cattle mortality

More than 30 livestock operations surround the reservation within the buffer zone (Figure 9), making Ma'iingan-livestock conflict an area of concern in Ma'iingan conservation. Many factors go into whether a population of Ma'iinganag shows a preference for livestock or for their natural prey. In some cases, high populations of a single natural prey species are less appealing to Ma'iinganag than livestock predation, but multiple and smaller populations of native ungulates will draw Ma'iingan more than farm animals will (Treves et al., 2004; Meriggi and Lovari, 1996). One reason for this predation trend may be that a single species experiencing constant predation from Ma'iingnag may learn more quickly how to evade the predator. For example, Waawaashkeshi retain instinctual responses to lower their vulnerability to predation (Nelson and Mech, 1994). Domesticated animals, though, have lost their ancestor's natural defenses against predation, thanks to selective breeding (Smith-Thomas, 2016). This presents an argument for returning historically native cervids, such as Omashkooz (American elk; *Cervus elaphus*), to Mashkiiziibing.

A three-year Minnesota study of Ma'iingan movements showed that the majority of instances of the animal on pasture lands were by chance passing (Chavez and Gese, 2006). These results were based on comparisons to simulations of what random activity would look like in Ma'iingan movement. Not all Ma'iingan visits to livestock in entailed a case of depredation. During the three years of the study, eight young or vulnerable farm animals were killed by Ma'iingnag (Chavez and Gese, 2006). Chance passing of livestock land in the pursuit of natural prey, though, can result in livestock depredation due to the fact that they are an easier meal for Ma'iingan (Amirkhiz et al., 2018).

Habitat variables and secondary prey may influence whether Ma'iingan pursues livestock or natural prey. There have been studies that both show Ma'iingan to prey more heavily on livestock despite a healthy availability of natural prey (Treves et al., 2004) and show Ma'iingan to prey more heavily on natural, secondary prey despite livestock being more readily available (Chavez and Gese, 2005). In the first study, the reason for heavy livestock predation was hypothesized to be due to the landscape consisting largely of pasture rather than being intermingled with forest, wetlands and open water (Treves et al., 2004; Treves et al., 2011). In the second study Wazhashk (Muskrat; *Ondatra zibethicus*) made up the second largest percentage of Ma'iingan's

diet, which may indicate that presence of secondary prey helps to reduce livestock predation (Chavez and Gese, 2005). More research is needed to understand wolf predation on livestock, its influencing variables, and its prevention. Still, it seems that conserving biodiversity, and thus giving Ma'iingan varied prey options, may help to prevent Ma'iingan conflict with livestock.

It's also important to note that Ma'iingan predation on livestock and native prey may be overemphasized by those who have bad feelings toward Ma'iingan. Depending on the location, Makwag may prey on just as many Waawaashkeshi fawns as Ma'iingan does (Kunkel and Mech, 1994). Wiisagi-Ma'iingan are known to be a significant cause of sheep and goat depredation (Mitchell, Jaeger, and Barret, 2004).

Coexistence

Encouraging coexistence with Ma'iingan is essential to an effective relationship plan, because human caused mortality is the number one killer of Ma'iingan in Wisconsin (Treves et al., 2019). Additionally, Ma'iinganag and other predators can kill and eat domestic animals, including sheep, cows, chickens, and dogs. It doesn't happen often, but it can have great impacts to the individual experiencing the loss. Any conflicts with Ma'iinganag or other predators in Mashkiiziibing or within the buffer zone surrounding the reservation shall be reported to the MNRD Wildlife Specialist (see appendix for contact information) within 24 hours of the occurrence by either the individual or the immediate responding agency.

In order for conflict investigations to remain consistent, MNRD will follow the verification procedures provided by APHIS-WS and the WDNR and will ensure all parties are notified of predator-livestock conflict in a timely manner. Authority to make reactive decisions after Ma'iingan conflict in Wisconsin (outside of reservations) is held by the Wisconsin Department of Natural Resources (WDNR). Authority to make reactive decisions after Ma'iingan conflict on Mashkiiziibii lands is held by the MNRD. On private lands within the exterior boundaries of Mashkiiziibing and within the designated buffer area surrounding the reservation, authority shall be shared between the State and MNRD.

If a depredation does occur, all traffic in the vicinity must be kept to a minimum and the depredated animal must be covered with a tarp until designated staff are able to arrive and complete a thorough investigation. Photos shall be taken of the incident and an incident report shall be completed and kept on file at the MNRD. Copies of these reports shall also be provided to all parties involved in the conflict, and copies of reports from other agencies shall also be collected and placed on file at the MNRD.

If Ma'iinganag are again delisted federally, private landowners will have the right to shoot and kill Ma'iinganag in the act of killing, wounding, or biting a person's domesticated animals on their own private property as stated by Wisconsin NR code 10.02(1)(b). In this event, the Mashkiiziibii Wildlife Specialist and appropriate staff from WDNR and APHIS-WS must be notified immediately by the landowner or current caretaker of the property where damage has occurred to investigate the scene. See Appendix D for contact information. Any Ma'iinganag killed for the above listed reasons shall not be kept by the responsible party. All Ma'iinganag shall be respectfully handled by the Mashkiiziibii Wildlife Specialist and/or the MNRD Tribal Game Wardens.

The Tribe does not provide financial assistance for animals lost to or injured by Ma'iinganag. The MNRD can offer assistance and education on prevention tactics and on state and federal reimbursement programs. Conflict issues will be dealt with on a case by case basis. As a federal agency, APHIS-WS will co-investigate any depredation occurring within the exterior boundaries of the reservation as well as any occurring within the designated buffer area surrounding the reservation with the Mashkiiziibii Wildlife Specialist.

Preventing and Responding to Depredations on Livestock

A goal of MWP is to help identify non-lethal solutions to prevent predator-livestock conflict. The killing of individual animals that may have caused a depredation can lead to more issues, instead of effectively protecting livestock (Treves et al., 2015). Ma'iingan packs may break up if a member, especially the breeding

female, is killed (Treves et al., 2015). The breakup of a Ma'iingan pack can lead to young, dispersing Ma'iinganag or to wisagi-ma'iingan replacing the pack's niche. Young, dispersing Ma'iinganag have been shown to be more likely to go after livestock (Vucetich et al., 2013). A more promising solution is to understand the individual predators we share the landscape with and to establish an understanding with them that livestock are not acceptable prey items. This can be done with a menu of husbandry and deterrent practices.

The key to determining a long term, non-lethal solution is to determine the mechanism that is driving these depredations to occur. The impact that Ma'iinganag have on farms across Ma'iingan country is minimal compared to other negative impacts, but to one farm that has repeated depredations by Ma'iinganag, it can be emotionally and financially devasting (Breck and Meier, 2004). After an investigation has occurred in cooperation with MWP, APHIS-WS, and WDNR, the cooperating agencies will work with the landowner on site to develop a Depredation Prevention Plan with a list of recommendations to reduce the future risks of depredations. Recommendations will vary depending on the landowner and the circumstances. The Mashkiiziibii Wildlife Specialist is also available for depredation prevention consultation before and incident has occurred. This may entail signing an agreement between MWP and the livestock owner to lend out deterrents such as light makers and noise makers when available, free of charge.

In 2019, Abi Fergus began her master's education at University of Wisconsin-Madison in the Nelson Institute and Carnivore Coexistence Lab. She studied the potential of non-lethal deterrents to keep Ma'iingan and other predators away from livestock operations surrounding the reservation. By the 2023 update of the Ma'iingan Plan, findings from our research will be available to inform future carnivore-livestock coexistence on the reservation and in the buffer zone.

Disturbance Protection

Studies have shown that Ma'iinganag do not tolerate human activity around den sites (Paquet and Carbyn, 2003). MWP will establish a 1.5 mile (2.4 km) buffer around known, active Ma'iingan den locations from March 1st to July 1st. Since pups are more mobile later in summer, and since packs usually have multiple rendezvous sites, there will be no human disturbance restrictions on rendezvous sites. The buffer area around den sites will be considered when MNRD staff reviews proposed timber sales, development proposals, and certain access permits.

Incidental Ma'iingan Capture or Mortality

In the event of a trapper incidentally catching Ma'iingan, it shall be immediately released or the aid of Mashkiiziibii wardens and wildlife specialist is to be immediately requested. In the event that a dead Ma'iingan is found anywhere in Mashkiiziibing or within the buffer area surrounding the reservation, the MNRD Wildlife Specialist must be notified immediately by the party that found Ma'iingan or by the immediate investigating agency, whether it be APHIS-WS or WDNR. Depending on the location of Ma'iingan, other authorities may also need to be notified. Upon notification, the scene will be investigated by the proper authorities and Ma'iingan's remains will be handled respectfully by MWP.

Any Ma'iinganag found deceased in Mashkiiziibing shall be handled in a respectful way by MWP. Samples may be taken from individuals if deemed necessary for biological studies or law enforcement investigations. MWP will cooperate with a certified lab for necropsies and biological sampling of individuals. Some furs and skulls may be kept for educational and cultural purposes.

How to Obtain a Ma'iingan Fur

Each year, a number of Ma'iinganag are obtained by the WDNR. These Ma'iinganag are either found dead (during periods of delisting) or taken legally by lethal abatement methods conducted by APHIS-WS or private landowners off-reservation. These Ma'iinganag can be made available for educational or cultural uses.

Mashkiiziibii members interested in obtaining Ma'iingan's fur or any parts of Ma'iingan should contact the Maskiiziibii Wildlife Specialist. Distributions of Ma'iingan's fur shall happen on a first come first serve basis and will ultimately need to be approved by the Mashkiiziibii Tribal Council.

Education and Outreach

MNRD shall use a variety of media to help keep the community informed about Ma'iingan in and outside of Mashkiiziibing. These media will include information at public events held by MNRD, updates in the MNRD quarterly newsletter, and information on the Tribe's website. Changes to the Ma'iingan Relationship Plan will also include at least one public meeting to enable the community to comment on the proposed changes (Appendix E). To stay updated on reservation Ma'iingan visit the wildlife website at http://www.badriver-nsn.gov/wildlife/, read Common Ground (http://www.badriver-nsn.gov/news/) the department's quarterly publication, or contact the Wildlife Specialist.

Research and Monitoring of Ma'iinganag in Mashkiiziibing

MWP has been monitoring the Ma'iingan population on the reservation since 1996. The Tribe has worked cooperatively in this effort with the WDNR, USFWS, and APHIS-WS. Methods MWP currently uses are as follows: winter track surveys, howling surveys, scat surveys, and keeping a Ma'iingan observations log book.

Winter track surveys and howling surveys are valuable tools for monitoring the reservation's Ma'iingan population. MWP follows similar winter track survey and howling survey protocols established by the WDNR, which helps in our joint effort to monitor Ma'iinganag both on and off reservation. The protocols for these surveys can be found in Appendix C and the department welcomes any Mashkiiziibii member to participate in these surveys independently or along with the Wildlife Specialist. This data collected by MWP is shared with WDNR and other cooperating agencies to help paint the full picture of how the Ma'iingan population is doing in the Great Lakes region.

MWP also keeps a Ma'iingan observation log. When people report a Ma'iingan sighting on the reservation, the department obtains information on the location, number of animals, color, and size. Following a reported sighting, the Tribal Wildlife Specialist or a Tribal Warden will investigate the sighting and obtain information that can be used to help estimate the reservation's Ma'iingan population. MWP also collects trail cam photos from hunters on the reservation to document Ma'iingan sightings. Photos can be emailed to the Wildlife Specialist at wildlife@badriver-nsn.gov or delivered to the MNRD office in the Chief Blackbird Building.

Scat is collected by MNRD Wildlife program staff when found anywhere on the reservation. This scat can be used to monitor Ma'iingan population health by examining it for viruses, parasite levels, diet, and inbreeding. MWP will coordinate with a certified lab for the analysis of the samples if/when funding is available.

Future Ma'iingan Program Needs

MWP will continue to work with state and federal agencies as well as neighboring landowners in the monitoring of and relationship building with the local Ma'iingan population. MWP will put a continued effort into building a citizen monitoring network to aid MWP in acquiring more knowledge about the resident Ma'iingan packs. Conducting howl surveys is a great opportunity for the community to connect with brother Ma'iingan and citizen monitoring would help relieve the wildlife program to diversify its wildlife monitoring work. Citizen monitoring can also be used as an education/outreach tool for children and local school groups. There is a continued need to study Ma'iingan's local diet by analyzing how many Amikwag and Waawaashkeshiwag Ma'iingan is eating from season to season. Unnatural sources of food such as bait piles and livestock carcass pits have been documented on or near the reservation, further justifying the importance of a diet analysis. Ma'iingan diets have not been studied in Wisconsin since 1980, when the population had not begun its large climb in the 1990s.

With this update to the relationship plan, MWP is moving away from putting GPS and VHF collars on brother Ma'iingan. This is an important time to demonstrate how we can come to understand Ma'iingan with tracks, scat, howls, and trail camera pictures, rather than by using invasive monitoring methods that entail some risk to Ma'iingan. Potential research partners who honor the Anishinaabe value of reciprocity are encouraged to reach out the MWP with proposals for collaborative research.

Appendix A. Overview of ESA status and state and tribal Ma'iingan conservation

ESA: Western Great Lakes Distinct Population Segment of Gray Wolves

As of the 2019 update of this plan, Ma'iinganag in the Great Lakes Region were federally protected under the Endangered Species Act. When Ma'iingan is delisted, it is the responsibility of states and of tribes to conserve Ma'iingan cooperatively.

Figure 11: Western Great Lakes Distinct Population Segment

Summary Wisconsin's Ma'iingan Relationship Plan (1999)

In 1999, the WDNR developed a Wolf Management Plan to help formalize Ma'iingan relationship in the state. Many components of the plan could not be implemented until after federal delisting occurred. Ma'iinganag in Wisconsin were briefly delisted in both 2008 and 2009, but subsequently relisted following legal challenges, before delisting again in 2012 and then relisting in 2014.

The WDNR chose to use management zones as part of the state-wide Wolf Management Plan. There are currently four wolf management zones in the state of Wisconsin: Zone 1 – The Northern Forest Zone, Zone 2 – The Central Forest Zone, Zone 3 – The wolf buffer area, and Zone 4 – southern area that the State presumes has little to no opportunity for colonization by Ma'iingan packs. Mashkiiziibing is located in Zone 1. Zone 1 includes 634 square miles of Indian reservations, which, in most cases, will remain as protective areas

for Ma'iinganag. Zone 1 is considered to have the most suitable Ma'iingan habitat in the state, because it is a mostly forested landscape with few agricultural and urban areas.

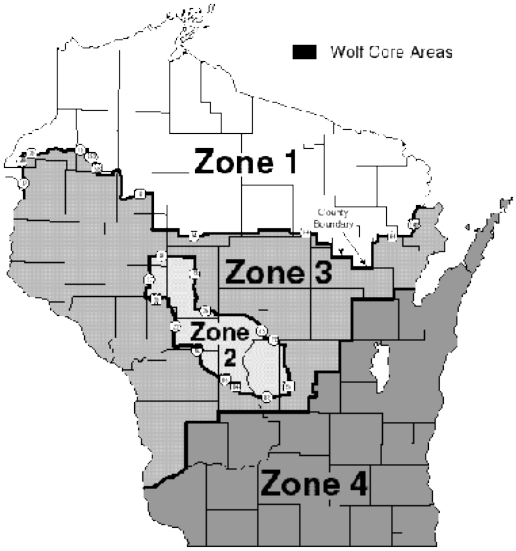

Figure 12: Wolf management zones as documented in 1999 Wisconsin Wolf Management Plan

From 2012 to 2014, when Ma'iingan was delisted in the Great Lakes region, the WI DNR primarily used lethal control at what the agency confirmed as depredation locations. Control of depredating Ma'iinganag can be done by landowners/occupants acting on private land under WDNR permit or by government trappers; landowners can also kill Ma'iinganag that are in the act of attacking pets or livestock on their land under NR 10.02(1)(b).

The WDNR's minimum population goal for the state is 350 Ma'iinganag. Ma'iinganag will be relisted as threatened by the state if the population falls below 250 Ma'iinganag for three years, and as endangered if they fall below eighty. As long as the state's Ma'iingan population remains above target levels, lethal management will continue in areas with a history of depredating Ma'iinganag or a high probability of Livestock-Ma'iingan conflict.

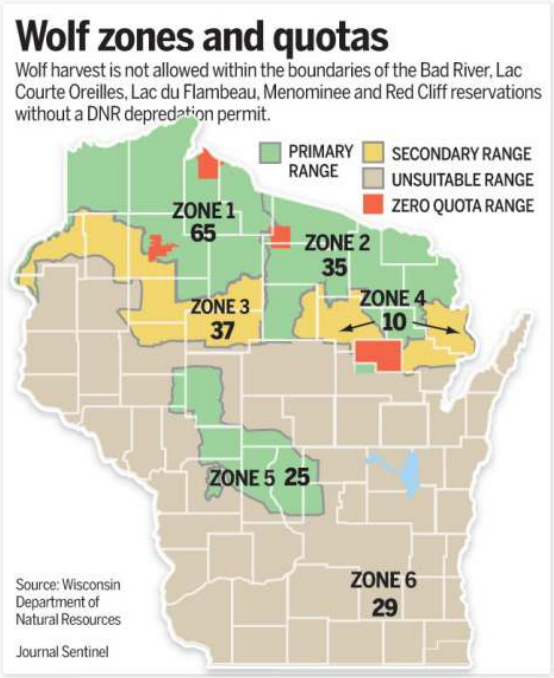

Figure13: 2012 WDNR Proposed Ma'iingan Harvest Zones and Quotas. The quotas are subject to change on an annual basis.

A Ma'iingan Season in Wisconsin

On January 31st, 2012 Senate Bill 411 was introduced by Senators Moulton, Holperin, and Lasee. The bill was related to the hunting and trapping of Ma'iinganag in Wisconsin. On March 30th, 2012 the bill was

presented to the Governor Scott Walker. The bill is now known as 2011 Wisconsin Act 169 which was published on April 16th, 2012. On October 15th, 2012, Ma'iingan hunting and trapping began under a permit/quota system with the exception that the following reservations were closed to harvesting: Mashkiiziibii, Red Cliff, Lac Courte Orielles, Lac du Flambeau, Menominee, and Stockbridge-Munsee.

The Wisconsin Natural Resources Board (NRB) chose a total harvest quota for the 2012 season to be 201 individuals. This quota predicted a reduction in the state Ma'iingan population by 14%. WDNR divided the state into six zones excluding the six reservations previously mentioned, and set there harvest goals for each zone. Twenty percent of the known minimum Ma'iingan population in zones one, two, and five would be harvested, forty percent of zones three and four, and seventy five percent of zone six would be harvested. The percentage was set high for zone six because this is deemed as unsuitable Ma'iingan habitat by the state of Wisconsin due to probability for human-Ma'iingan conflict.

The WDNR then took the quota of 201 individuals and subtracted half of the harvest quota in the ceded territories for the tribes to claim based on the LCO vs. Voigt case requirements. Half of the ceded territory quota amounted to 85 leaving the final 2012 Ma'iingan season quota at 116 individuals. The quota of 116 animals established for state harvesters was reached by December 23rd, 2012; no WI tribe allowed on or off-reservation Ma'iingan seasons for their members in 2012.

The total known human caused mortality of Ma'iinganag for 2012 was 243 individuals. There were 117 killed under the 2012 Ma'iingan hunt, 76 under depredation controls (including landowner permits), 24 documented vehicle collision, 21 known illegal kills, and 5 unknown mortalities. The minimum population count for the 2011-2012 tracking season ranged from 815-880. The midpoint of this would leave use with a minimum population estimate of 847, which would leave us with a 29% human caused mortality of the 2012 minimum population count. Now keep in mind that is a minimum count and does not include pups that were born in the spring of 2012.

Following similar hunts that took place in the modern State of Michigan, a number of well-respected ma'iingan researchers collaborated on a review of the lack of scientific or ethical justification behind the way in which the Michigan Ma'iingan hunts were conducted (which is similar to what occurred in Wisconsin). The Michigan Department of Natural Resources explained that the purpose behind its 2013 Ma'iingan Harvest season was to reduce the potential of conflict between Ma'iingan and livestock or Ma'iingan and humans. The MI DNR did not substantiate its harvest plan with any scientific evaluation. Employing scientific research, the authors of the paper pointed out issues in the reasoning behind and execution of the Michigan Harvest Season. The researchers concluded:

- Hunting Ma'iingan doesn't teach other Ma'iinganag not to visit farms
- In order to reduce the amount of depredations that occur on farms, an unacceptable 20% of the Ma'iingan population would have needed to be hunted
- The Michigan Harvest Plan does not include adaptive management language to change the plan in response to how the hunt would affect the Ma'iingan population

Wisconsin Landowner Ma'iingan Control Permits

When Ma'iingan is delisted in the Western Great Lakes Distinct Population Segment, the WDNR has had authority to issue permits for the shooting or trapping of Ma'iinganag on privately owned property. The criteria for obtaining a Ma'iingan control permit are as follows:

- At least one verified depredation has occurred within the last 2 years on owned or leased land;
- A verified depredation has occurred within one mile of the applicant's property with vulnerable animals within the current calendar year;

- Human safety concern from Ma'iinganag exists on the property as determined by U.S. Department of Agriculture Wildlife Services or WDNR; or
- Harassment of livestock is occurring and based on the judgment of Wildlife Service's a permit should be issued.

Permits are usually valid for 90 days after issuance and can be renewed by the WDNR. Hunting and trapping of Ma'iinganag is allowed under these permits, often with no limit to the number of animals to be removed or destroyed. The following are additional permit conditions:

- Authorized participants are the permittee and resident family members. Up to two additional persons may be designated at the time of permit issuance to assist with the removal of Ma'iinganag. Assistants must be listed on permit.
- Shooting hours will be normal hunting hours, unless Ma'iinganag are in the act of killing or attacking domestic animals.
- Baiting is not allowed. All livestock that is killed must be disposed of pursuant to Section 95.50, Wisconsin Statutes.
- Shooting and trapping will only be permitted on land owned or leased by the permittee.
- All Ma'iinganag shot or trapped must be reported within 24 hours and turned over to the Department.
- A trapping license is required for trapping of Ma'iinganag as are specific trapping techniques and equipment which will be conditions of any trapping permits issued.

As a result, the MWP works with the state and APHIS to investigate reports of potential Ma'iingan depredation both within the reservation's exterior boundary, and within the surrounding buffer zone. While lethal depredation control may be permitted when depredation is verified and non-lethal

methods are considered un-effective, it may also not be approved if the impacts to local packs is deemed exclusive.

Appendix B. Ma'iingan Survey Protocols and Forms

Winter Carnivore Tracking Survey Form and Protocol

Developed using standardized survey methods provided by Wisconsin Department of Natural Resources.

(Wydeven, A., et. al. 2004. Guidelines for Carnivore Tracking During Winter in Wisconsin. Wisconsin Department of Natural Resources. http://www.dnr.state.wi.us/org/land/er/mammals/volunteer/pdfs/tracking_guidelines.pdf)

Introduction

Since wildlife does not know our political boundaries, it is important to work in cooperation with neighboring agencies to better monitor and assess population trends. To standardize survey methods, the tribal survey methodology was modeled after the already existing guidelines provided by the Wisconsin Department of Natural Resources. However, some of the guidelines have been modified to better suit the need of the reservation.

Tools Needed

- Tracking guide book(s)
- Detailed map of the survey area
- Data sheet, clipboard, and pencils
- 6 in ruler and tape measure
- Camera
- GPS

Completing the Data Forms

-Please make sure forms are ***completely*** filled out. If you have any questions pertaining to the forms please call the wildlife specialist @ 715-685-7840 ext 1554

Surveyor(s): Names of people conducting track survey

Date: Month/Day/Year track survey was completed

Survey Block ID: See attached map for survey block ID's.

Survey Start Time: Time survey began.

End Time: Time Survey ended that day.

Temperature: Temperature at the beginning of the survey.

Time of Last Snow Fall: If it snowed within the last 48 hours, write down how many hours it has been since the last snowfall. If it hasn't snowed for more than 48 hours record the number of days since last snowfall.

Snow depth: Record the total snow depth in inches. Avoid areas of plowed, drifted, or under trees were snow depth is affected.

New Snow Depth on Road: Record amount of snow present on the road of survey in inches. This may change as you move onto new roads make sure to record this in the comments section.

Amount of snow from last snowfall: Record in inches how much snow was received our last snowfall.

Percent Cloud Cover: Circle percentage nearest to the amount of cloud cover.

Rate Track Conditions:

Poor: It is snowing heavily, hasn't snowed in a while, heavy crust on snow layer impacting amount of tracks present.
OK: Tracks are visible but lack detail near road, need to follow off road a little ways to identify.
Good: Tracks register well in the snow. Some lack details necessary to distinguish between similar species.
Excellent: Tracks register well and show a good amount of detail. Tracks are easily distinguishable.

When you Encounter Tracks

1) Consult your tracking guide to identify the species that made the tracks.
    a. Some species tracks may look similar so make sure to pay close attention to the gait pattern (sequence of foot movements).
    b. Sometimes it may be necessary to follow the tracks into the woods a short distance to find a better track that is more easily identifiable.
2) When Ma'iingan tracks are encountered follow the protocols in the Ma'iingan tracking guidelines (see attached). A photo of the track next to the ruler should be taken as well as a GPS location.
3) If rare species such as: Elk, Moose, Cougar, Canada Lynx, or wolverines are identified. A GPS location should be taken at the site. (See below for GPS location protocol)
4) For all species but Ma'iinganag, all tracks encountered within 0.3 s of each other should be recorded as one animal.
    a. For Ma'iinganag follow tracks backward and forward until you can get a good count of the number of animals present. Ma'iinganag will often loop around and follow portions of a route more than once, so what appears to be the tracks of four animals may only be two Ma'iinganag.
5) Record any other related sign encountered while tracking. (Carcasses killed or scavenged by carnivores, signs of urinations (raised leg urination or squat urination), evidence of blood in the urine, scat…)

6) If you are uncertain about a track record UNK on the data sheet, record the location, and take a few photographs and ask the Wildlife Specialist about it.

Key Points to Remember

- Canines (dog family) vs. Felines (cat family)
  - To distinguish the difference between these tracks check for claw marks. Members of the cat family have retractable claws and rarely show claw marks in the snow. If they do they appear thin and knifelike.
  - The heel pad on a cat will be asymmetrical and have 3 similar sized lobes on the bottom of the track. A dog's heel pad will be symmetrical, the lobes on the bottom will not be similar in size, and the top of the pad will be more round and pointed.
- Measure any small fisher tracks to make sure they are not marten tracks. Fisher tracks will generally be at least 1.6 inches long and 1.5 inches wide.

Ma'iingan Howling Survey Form and Protocol

HOWL SURVEYS FOR MA'IINGANAG IN WISCONSIN

By Adrian P. Wydeven

Howling surveys are conducted to determine general location, home site locations, general abundance and pup production in Ma'iingan packs. Use the article by Harrington and Mech (1982, J. Wildl. Manage. 46: 686-693) as a general guide on doing Ma'iingan howling surveys.

Surveys usually should be done from June 20 through October, with July and August being the best period. Time of day should be from ½ hour after sunset until 1:00 or 2:00 a.m. Areas to be covered should consist of a series of roads that traverse or surround the likely territory of Ma'iinganag. Howl attempts should be made at about 1.5 mile intervals, but can be modified by 0.2 to 0.3 miles to avoid hollows, occupied residences or noisy stream edge, and to take advantage of higher elevations. Also, make special attempts to howl from most intersections.

At each stop, walk about 100 feet from your vehicle. Start off with 4-5 quiet howls for about 25-30 seconds. Wait 90 seconds for a response. If no response, give 4-5 loud howls for 25-30 seconds. Again, wait 90 seconds for a response. Give a second series of loud howls followed by 90 seconds of waiting time if no response occurs. If no responses after this third howling attempt, drive to your next stop.

Use of the Howl Survey Form

General Location: List area being covered, especially the county and pack name.

Start Location: Write the legal description of the first howl attempt stop.

End Location: Write the legal description of the last howl attempt stop.

Date: Date of survey; remember that if you go past midnight the date will change.

Temp: Temperature at start of survey.

Skies: List percentage of cloud cover.

Precip: Indicate any precipitation falling; if moderate to heavy rain occurs, stop survey.

Wind: Indicate approximate wind speed; if winds exceed 8 miles/hr. stop survey.

Previous Day(s) Weather: List high and low of survey day and any precipitation that occurred

Observer(s): List all persons taking part in the survey.

Road Name: Write the name of each road you are surveying and give the odometer reading when you first enter a road.

Other Columns: At each stop, write the odometer reading and time when you initiate the howling attempt. If you get a response from Ma'iinganag write down the time when Ma'iinganag respond to your howling attempt, number of Ma'iinganag responding, direction of response, exact location (legal description) of response, and any comments. Generally the number of Ma'iinganag recorded should be 1, 2 or 2+ adults and/or 1, 2 or 2+ pups; beyond 2 adults or 2 pups it is impossible to accurately count the Ma'iinganag unless you actually get to see them. When you get no responses, under "Time Response" write "none". You may want to record responses from other animals such as owls or coyotes under "Comments". If you are not sure whether you are hearing coyotes or Ma'iinganag, write down that you are not sure.

Totals: List the total miles from the first to last stop; list the total number of stops at which you attempted howls; list the total number of responses you received under "Time Response"; and list the estimated number of Ma'iinganag responding under "Ma'iingan No.".

Equipment

Pen or pencil, clipboard, data sheet(s), watch, flashlight, compass, map of study area at scale of 1:150,000 or larger, and tape recorder with empty tape and Ma'iingan tape (optional).

Do's and Don'ts

Avoid using brights when driving through open country.

Don't attempt to shine flashlights at Ma'iinganag that may approach you.

Attempt to be as quiet and inconspicuous as possible.

Turn off all lights and avoid using flashlights when you arrive at your stops.

Never attempt to walk into an area from where you hear howling.

Don't take a large number of people with you; limit the number of people on the survey to 4 or less.

Generally only one person should do the howling, but you can trade off so no one person needs to do all the howling.

Generally no more than one survey per week per territory should be conducted; unless there is need to gather additional data.

When you have received a response, don't stay at a site too long, and do not keep howling at the same group.

Avoid disclosing exact locations of howling responses to people outside of your survey group.

4. Cooperator's address:
5. Location of work to be performed:

I, the undersigned cooperator or cooperator's representative, do hereby give my consent and concurrence to the Mashkiiziibii Wildlife Program (to include its employees) to use at the site described in 5 the following methods and devices (owned by Mashkiiziibii Wildlife Program):

I, the cooperator or cooperator's representative, have been informed of the methods and the manner in which the devices listed in the above section will be used, and of the possible hazards associated with their use. I understand that Mashkiiziibii Wildlife Program (to include its employees) will: exercise reasonable precautions to prevent injury to animal life; guard against the mishandling of devices and materials; and exercise due caution and proper judgement in all wildlife coexistence operations. I understand that Mashkiiziibii Wildlife Program will provide copies of records or record information promptly upon the property owner's or cooperator's request. I understand that Mashkiiziibii Wildlife Program may collect Global Positioning System (GPS) coordinates, predator presence, and deterrent effectiveness data at the project site as part of anonymized research. I understand that Mashkiiziibii holds insurance for its employees which will cover any accident that may occur on the property outlined in line 5, leaving me with no liability for the potential injury of a Mashkiiziibii employee.

In consideration of these understandings and of the benefits to be derived, I, the cooperator or cooperator's representative assume responsibility for injury to my property under my control, when said injury is not the result of negligence on the part of Mashkiiziibii Wildlife Program; and to give adequate warning of possible hazards to persons I authorize to enter onto my land. Further, in recognition of the benefits to be derived from the use of specified methods and devices authorized by this Work Initiation Document, I, the cooperator or cooperator's representative, agree not to concurrently use or allow to be used upon lands covered by this Work Initiation Document lethal methods. This will allow for the collection of data on the effects of non-lethal deterrents alone. As part of this agreement, the cooperator agrees to provide Mashkiiziibii Wildlife Program a brief review of whether they found the deterrent to be beneficial, based on the impact or lack of impact they saw on their domesticated animals and on predators, within a month of the removal of deterrents.

Appendix E. Public Comment opportunities for 2019 Update

The first update of the Ma'iingan Relationship Plan was delayed by a year, partially due to a staffing turnover in the wildlife program. Efforts were made to gain community knowledge and input for the update of this plan through the following events:

In November of 2018, former Wildlife Specialist Lacey Hill-Kastern opened a call for public comments for the update of the Ma'iingan Relationship Plan from November 1, 2018 through November 30, 2018.

On October 23, 2018 the Mashkiiziibii Wildlife Program hosted an event at the Casino to gather input for the Ma'iingan Relationship Plan and to discuss a response to Chronic Wasting Disease. Thirteen community members attended this event and mentioned Ma'iingan possibly defending the reservation against Chronic Wasting Disease, but the community members were largely focused on gaining an understanding of Chronic Wasting Disease at this meeting.

From July to August, 2017 current wildlife specialist Abi Fergus worked for Mashkiiziibii as an intern for the wildlife program to collect input for and scientifically review the Ma'iingan Relationship Plan. Fergus interviewed local wolf biologists, livestock owners within the reservation and buffer zone, and tribal members- particularly elders. Fergus has regularly attended elder lunches since this internship to gain insight from Mashkiiziibii elders. Fergus provided a report of her findings to former wildlife specialist Lacey Hill-Kastern as well as her senior thesis, which was written based on her recommended changes to the plan.

Appendix G. Mashkiiziibii Tribal Council Resolution Approving Mashkiiziibii Ma'iingan Relationship Plan

BAD RIVER BAND OF LAKE SUPERIOR TRIBE OF CHIPPEWA INDIANS

CHIEF BLACKBIRD CENTER

P.O.Box 39 • Odanah, Wisconsin 54861

Resolution No. 12-17-19-248

Approval of the 2019 update to the Mashkiiziibii Ma'iingan Relationship Plan

WHEREAS, the Bad River Band of Lake Superior Tribe of Chippewa Indians is a federally recognized Indian tribe with a Constitution enacted pursuant to the Indian Reorganization Act of 1934, 25 U.S.C. Sec. 476; and

WHEREAS, Article VI, Section 1(a) of the Constitution authorizes the Tribal Council to negotiate with Federal, State, and local government on behalf of the Band; and

WHEREAS, Article VI, Section 1(n) of the Constitution directs the Tribal Council to encourage and foster the arts, crafts, traditions, culture, wildlife, and natural resources of the Band, which necessarily includes enhancement and protection of the water resources within the boundaries of the Reservation; and

NOW, THEREFORE, BE IT RESOLVED that the Tribal Council hereby adopts the 2019 update to the Mashkiiziibii Ma'iingan Relationship Plan

Certification

I, the undersigned, as Secretary of the Bad River Band of Lake Superior Tribe of Chippewa Indians, an Indian Tribe organized under Section 16 of the Indian Reorganization Act, hereby certify that the Tribal Council is composed of seven members, of whom 7 members, constituting a quorum, were present at a meeting hereof duly called, noticed, convened, and held on the 17th day of December, 2019; that the foregoing resolution was duly adopted at said meeting by an affirmative vote of 7 members; 0 against; and 0 abstaining, and that the said resolution has not been rescinded or amended.

Jay McFee

Re: Draft Wisconsin Wolf Management Plan

Dear Mr. Payne:

The Voigt Intertribal Task Force (Task Force) of the Great Lakes Indian Fish and Wildlife Commission (GLIFWC) submits these comments on the Draft Wisconsin Wolf Management Plan (Plan). These comments have been prepared by GLIFWC staff on behalf of the Task Force and are submitted from an intertribal, ceded territory perspective for the areas subject to the Treaties of 1837 and 1854 and are not intended to preclude comments by individual tribal governments. Moreover, notwithstanding any authority the Wisconsin DNR may exercise, these comments in no way intend or should be construed to imply a diminishment of any sovereign authority or responsibility of GLIFWC's member tribes to determine and undertake any appropriate course of action regarding Ma'iinganag (wolves) according to Anishinaabe teachings and traditions.

Wolves are beings of great significance to the Anishinaabe people. Ma'iingan is a clan animal, sacred in Anishinaabe beliefs. In the Anishinaabe creation story, we are taught that Ma'iingan is a brother to Original man. The two traveled together throughout the earth naming all things. When this task was completed, the creator said that the two had to take separate paths but indicated that whatever happened to one would happen to the other. Each would be feared, respected, and misunderstood by the people that would later join them on earth. We thus learn that the survival of the Anishinaabeg as a people is tied to that of Ma'iingan – as goes the fate of one, goes the fate of the other.

Consequently, in addressing this matter on behalf of the Anishinaabe communities that they serve, the Task Force must do no less than fully support efforts to protect, promote tolerance, and ensure healthy and abundant populations of wolves for it is the future of those communities that they also are considering.

The Task Force offers the following additional comments:

1. The Biological Services Division and the Division of Intergovernmental Affairs wish to acknowledge the time and effort put in by the DNR in meeting with and attempting to reach consensus on several important topics including discussion of tribal subzones and subzone limits.

2. The Task Force supports the Plan's goal of ensuring a sustainable wolf population that fulfills its ecological role. The adoption of a non-numeric population goal for wolves, rather than an arbitrary limit to their population, is more consistent with the tribes' relationship with Ma'iingan.

3. The Task Force recommends that western Taylor County be retained as core wolf range (zone 1) with the primary objective to ensure a healthy wolf population to fulfill its ecological role. This region was previously designated as core wolf range and provides ample habitat and public lands that support wolves while minimizing conflict.

4. The Plan follows an adaptive management framework. This will require monitoring accomplishments as well as shortcomings of the Plan's goals and objectives to evaluate their success and adjust as necessary. Adequate resources need to be devoted to this aspect of the Plan's implementation to be successful.

5. The Plan includes appropriate goals and objectives for education outreach efforts. However, falsehoods and misunderstandings continue to cloud wolf stewardship. Educational activities identified in the Plan must be a priority for implementation, should be adequately funded, and should include tribal perspectives.

6. The Task Force appreciates references to the *1837/1842 Ceded Territory Ma'iingan Relationship Plan*, which provides guidance for a reciprocal relationship with Ma'iingan that is consistent with GLIFWC-member tribes' cultural teachings. Additional information is provided in *Ojibwe perspectives toward proper wolf stewardship and Wisconsin's February 2021 wolf hunting season* (Gilbert et al. 2011, attached), which should also be cited in The Plan for its cultural perspective. These references and others provided in the Tribal Perspectives section of the Plan should also appear in the Literature Cited section of the Plan.

7. The Task Force opposes harvest of Ma'iingan. Legislative changes should be pursued to revoke Act 169 which limits WDNR management authority in the Plan. Nevertheless, the Task Force supports efforts in the Plan which aim to prevent harvest which exceeds established quotas and protect packs on tribal lands.

    a. The use of zone-specific permits and shortening the registration window to 8 hours will provide better control over harvest rates, making it easier to close areas to harvest before the state's quota is exceeded. The Task Force further recommends adoption of a "pulse rule" with respect to wolves - if wolf harvest exceeds the quota within a zone for two consecutive years, no harvest may occur in that zone in year three.

    b. The establishment of tribal subzones is a positive step towards acknowledging the tribes' sovereignty with respect to protecting wolves that reside on tribal lands. The Task force recommends the subzone limit for subzone 1B be set at 1 wolf. The recommended limit of 4 wolves is equivalent to the average pack size in the ceded territory and could allow for an entire pack to be harvested. The Task force further recommends that any lethal control of wolves within subzone 1B be applied toward the subzone limit for that year.

8. The training period for hounds should be limited to zones that are open for harvest to prevent unnecessary conflict between hunting hounds and wolves.

9. The ecological role of wolves in limiting the prevalence of CWD in Wisconsin's white-tailed deer and elk herds should be a research priority. However, uncertainty about the relationships between wolves and CWD prevalence should not preclude prudent stewardship. Wolf harvest should be limited where new CWD detections have occurred within wolf range, and along the southern edge of wolf range where CWD has not yet been detected to take advantage of this ecological service and research opportunity.

10. The Plan should respect how tribes may wish to handle any potential quota allocations if harvest is authorized by the state (see attached letter from Bryan Newland, Assistant Secretary, USDOI – Indian Affairs).

11. The Task Force strongly recommends reinstating two committees to advise wolf stewardship and keeping the technical committee restricted to technical experts from tribal, state, and federal agencies.

The Task Force and GLIFWC staff stand ready to assist in any way they can as Wisconsin DNR implements the Wolf Management Plan. We hope that Wisconsin DNR will maintain relationships with tribal representatives as the final Plan is implemented. To this end, the Task Force extends a standing invitation to Wisconsin DNR to discuss these issues at any Task Force meeting, which generally are held on the first Thursday of every month. Please let us know and we will assist with the necessary arrangements.

Thank you for the opportunity to provide these comments on the Draft Wisconsin Wolf Management Plan. If you have any questions, would like additional information, or would like to attend an upcoming Task Force meeting, please contact Miles Falck of our staff at (715) 682-6619 ext. 2124 or miles@glifwc.org.

Sincerely,

James Thannum
Acting Executive Administrator

THE RELATIONSHIP WITH MA'IINGAN

This document will attempt to describe the appropriate relationship between the Anishinaabeg and ma'iinganag (wolves) in the 1837 and 1842 ceded territories.

Of all the beings with whom the Anishinaabeg share Aki, there is no other with whom the people share a greater connection, and no other with whom the Ojibwe directly share a common and intertwined fate. As such, the long-term health of the People can only be assured when the ma'iingan population is healthy and vibrant as well.

The goals that are outlined in this plan were informed by a triad of understandings of ma'iingan: 1) traditional Ojibwe teachings; 2) Traditional Ecological Knowledge (TEK) that the Ojibwe have gained over countless generations of co-existing with ma'iingan; and 3) contemporary ecological, biological and social science. It is the intent of the Voigt Intertribal Task Force, who approved this document, that it be transparent about the underlying justifications for the goals it contains. As such, it is appropriate to begin with a summary of some of the primary teachings which informed these goals.

A Teaching: The Creation Story

"After plants, Kitche Manitou created animal beings, conferring on each special powers and natures."
Basil Johnston, Ojibwe Heritage

Ma'iinganag, like all animal beings, are part of the third order of creation. The rock, water, fire, and wind created in the first order needed to exist to create the places where the second order of creation, the plant beings, could grow and thrive. The lush and complex world created by the plant beings in turn made it possible for the earth to welcome the third order - the animal beings – that depend directly or indirectly on the plant beings for their own survival. Ma'iinganag are part of this third order, and are dependent upon all that came before or with them for their own chance at health and abundance.

Finally, in the fourth and final order of creation, the original human was lowered to the earth. This being was last because he was and remains the most dependent being of all, unable to survive without the gifts of the beings – often referred to as the more-than-human beings – that came before him.

The Creator directed Original Man to give names to all of the parts of creation. As Original Man did this, he learned much about creation, including the beauty, benefits, and interconnections of the beings. He also noticed that many of the animals had partners and were part of communities, while he was alone, and felt a loneliness in his spirit. When Original Man shared these observations with the Creator, the Creator responded by providing a ma'iingan for Original Man to walk and talk and play with, and he tasked Man and Wolf with visiting all the Earth's places together.

As Original Man and ma'iingan worked together to complete this formidable task they grew very close, as they came to understand the unique relationship they shared. It is often said they came to be like brothers, but others contend that even this powerful bond fails to capture the full nature of the relationship, saying that Wolf and Man were really one being, parts of a greater whole.

Thus, it must have come as a surprise or a shock when they completed their travels and returned to the Creator, to be told, "From this day on, you are to separate your paths. You must go your different ways. What shall happen to one of you will also happen to the other. Each of you will be feared, respected, and misunderstood by the people that will later join you on this Earth" (The Mishomis Book, Edward Benton-Banai, 2010). In many ways, this teaching of intertwined fates forms the ultimate foundation for the relationship between Anishinaabeg and ma'iinganag.

> *"And so, you Anishinaabe, if your brother ma'iingan passes out of existence you'll soon follow. You will die of great loneliness of spirit."*
>
> *Joe Rose Sr., Bad River*

A Teaching: The Original Treaties

When Anishinaabe people speak of the Original Treaties, they are talking about the treaties they made with the more-than-human beings they depend upon for survival. The early Anishinaabe people understood their dependency upon the earlier orders of creation. While those beings were not dependent upon humans, the People could not survive without the gifts the other beings provided. Fortunately, the more-than-human beings took pity on the humans and agreed to provide for them, but certain things were expected from the humans in return.

> *"And all the animals stepped forward and said what they would give to the people, and they did it out of love for the people that wanted to come live in the universe."*
>
> *Chairman Robert VanZile, Sokaogon Tribe*

Ma'iingan assumed many responsibilities, including teaching the Ojibwe how to survive on an often-harsh landscape; how to hunt; how to build stamina and work cooperatively; and importantly, how to raise young in extended family groups. They would also work to keep the deer herd healthy and help protect populations of plant beings important to the Ojibwe from over-browsing by deer. The Ojibwe responsibilities were to view ma'iingan as their relative, to treat them with respect, to think of their best interests, and to be appreciative and humble in accepting the benefits that wolves provide. And, as in the other treaties made with the more-than-human beings, the Ojibwe recognized that the proper relationship with all these beings demanded reciprocity and responsibility. Since treaties are recognized as "supreme law," these tenets have never changed. The Ojibwe not only still respect these treaties, but many tribes have joined other indigenous nations in reaffirming their commitment to them (Global Indigenous Council Wolf Treaty, Appendix 1; Figure 1). And in this context, it is important to acknowledge that wolves hold treaty rights, just like their Ojibwe brothers.

Figure 1. Winona LaDuke and Paul Demain with the Global Indigenous Council Wolf Treaty.

Co-existence with Ma'iingan

While these cultural teachings underlie the primary tenets of this plan, the application of those teachings is also informed by the TEK that the Ojibwe gained from sharing the land with ma'iinganag. Like Original Man, generations of Ojibwe learned about - and from - ma'iingan. Wolf recovery has allowed this learning to start anew in the 1837 and 1842 ceded territories; tribal members and tribal biologists are again being gifted by wolves, as they tell us more about themselves and provide new lessons on living in a good way.

The Ojibwe's successful co-existence with wolves provides an important contrast with the prevailing perspective brought to Turtle Island by Europeans, whose primary interest in wolves was eradication – something at which they proved very adept. While those interests are changing among many in the non-tribal public today, some still carry old biases toward ma'iingan and cling to unfounded myths about the nature and ecological roles of wolves. Of greater concern is that many of the most misinformed retain the greatest influence on state natural resource agencies, whose funding is generally derived from only a small portion (primarily hunters, trappers, and fishers) of the public they are supposed to represent.

Co-existence with wolves can yield understanding and appreciation. A deer hunter holding an overly-simplistic belief that since wolves eat deer, wolves are bad for the deer herd, may only see wolves in a negative light, while a hunter who understands the wolf's role in maintaining the long-term health of the deer herd by selectively preying upon the weak, injured, and diseased may appreciate the benefits wolves provide the herd – especially in the face of diseases like chronic wasting disease. A person only focused on the losses some livestock producers experience from wolves may not understand that most wolves do not kill livestock, or that hunting wolves offers few tangible benefits to Midwest ranchers. A person who is highly fearful of wolves may struggle to understand the minimal actual danger ma'iinganag pose to them and may not be aware that wolves may be reducing his or her chance of hitting a deer on the highway or getting a tick-borne disease. When the Ojibwe share their nuanced and complex relationship with ma'iingan, and illuminate it with new understandings, others may come to see wolves in a different light as well and learn that a healthy relationship with ma'iingan is good not only for wolves, but for humans.

> *"We reached the old wolf in time to watch a fierce green fire dying in her eyes. I realized then and have known ever since that there was something new to me in those eyes, something known only to her and to the mountain. I was young then and full of trigger-itch; I thought that because fewer wolves meant more deer, that no wolves would mean hunters' paradise. But after seeing the green fire die, I sensed that neither the wolf nor the mountain agreed with such a view."*
>
> *Aldo Leopold, Sand County Almanac*

Finally, in addition to the insights provided by the traditional teachings and TEK discussed above, this plan is further enlightened by the inclusion of understandings gained from contemporary science. Those understandings can offer insights on the myths often applied to wolves and re-enforce both the traditional teachings and TEK. This triad – cultural teachings, TEK, and contemporary science – all inform and support what follows in this plan.

GOALS FOR THE MA'IINGAN POPULATION

While the Ojibwes' goals for the ma'iingan population can be as numerous and detailed as the goals for their own communities, a small number of primary goals can capture the overarching desires for the ma'iingan population in the ceded territories. In very brief, this may be stated as having a healthy and ecologically functional ma'iingan population occupying all areas of suitable habitat. And while this plan is focused upon the 1837 and 1842 ceded territories, the tribes' hopes for the ma'iingan community do not stop at the ceded territory boundary.

Unlike state wolf management plans, which often attempt to use humans' objectives to define or limit what they consider suitable wolf habitat, this document recognizes that ma'iinganag themselves are best at determining what habitat and range is suitable for them. Thus, at a landscape level, ma'iinganag should be allowed to determine their range and population level. Only this goal allows ma'iinganag to completely fulfill their treaty with the Anishinaabe, for only at this level can they fully provide the cultural and ecological benefits the tribes depend upon, over the greatest area.

This goal also recognizes that ma'iinganag are only able to fulfill their responsibilities when the wolf population is healthy. In the Ojibwe world view, determining the health of the ma'iingan population involves much more than simply determining the number that exist. Like human communities, the demographics of the population are also important, as social structure is critical in wolf packs, so that wolves, like their human relatives, can pass down teachings and properly raise their young. Thus, demographics like wolf density and pack size should again be determined by wolves themselves, and not be altered by negative human influences.

Individual ma'iinganag should also be healthy, and not exposed to dangerous levels of environmental contaminants, or be subject to unnatural levels of diseases or parasites because of human activity.

The recreational harvest of wolves is both culturally abhorrent and incompatible with the goal of a healthy wolf population. In the Original Treaties, the Ojibwe agreed to take only what was needed, and most non-tribal hunters maintain a similar ethical code that contends that killing any animal should only be done for a legitimate reason. As is discussed later in this document, the reasons most often given for wolf seasons (human health and safety, impacts on the livestock or the deer herd, or to keep the population from growing "out of control") are not supported scientifically, and killing an animal to simply experience the act or gain a "trophy" runs counter to both the Ojibwe world view, and to most in the non-tribal community.

The tribes recognize that wolves – like other relatives – sometimes negatively impact some in the human community. While the tribes encourage efforts to reduce and address the losses some livestock producers incur, Ojibwe understanding necessitates preventative and non-lethal programs as a primary response in these situations. Lethal control should only be taken as a last resort, in a timely and targeted manner, in cases where evidence is clear that ma'iinganag were at fault and where non-lethal efforts are ineffective or unworkable. (For greater detail, see *Livestock and Pet Depredations*, below).

Should a state in the ceded territory nevertheless initiate recreational hunting and trapping seasons for wolves, there are several steps which must be taken by the state, including:

- Recognizing that ma'iingan living within reservation boundaries should be stewarded under the authority of the respective Tribe.
- Coordinating off-reservation depredation control efforts with individual tribes if they occur within 6 miles of a reservation or within an alternate buffer area established through consultation with an individual tribe.
- Monitoring wolf populations with a high level of precision and accuracy.
- Consulting and attempting to reach consensus with tribes on harvest quotas. Quotas must recognize the considerable uncertainty associated with population estimates. Quotas must be applied to all state-sanctioned taking, including depredation kill, otherwise lethal depredation control reduces the tribes' share of the quota. Harvest must not reduce the distribution or ecological function of wolves on the landscape. Finally, harvest quotas must not be exceeded, and the tribal portion must be respected.
- Closing public lands to wolf harvest until the state wolf harvest can be adequately controlled to meet these requirements and ensure protection of tribal interests.

In addition, ceded territory wolves should be stewarded as a part of a larger regional population. Ceded territory ma'iingan should connect healthy populations in Minnesota, Michigan, and the central sands region of Wisconsin.

Ma'iingan Population Trends

Ma'iingan is the Ojibwe name for the animal known in English as the wolf. Wolves in the Great Lakes region are sometimes commonly referred to as timber wolves, but this term is falling out of use, as it neither has specific meaning, nor accurately describes the habitat requirements of this being.

Western science also applies a unique Latin name to this being. However, the scientific classification of ma'iinganag in the 1837 and 1842 ceded territory has varied over time and is likely to continue to do so as new genetic analyses are developed and applied, and new understanding is gained and interpreted. Currently, wolves in the region are generally considered to be gray wolves, or *Canis lupus*, in the Latin nomenclature. For the purposes of this document, all wolves found in the 1837 and 1842 ceded territory are considered simply ma'iingan, without further differentiation.

Historical Distribution

The population and range of ma'iinganag in the 1837 and 1842 ceded territories has exhibited marked variability over the last two centuries. Wolves in this area were originally part of a much larger population that covered much of North America, including most of what is now the Lower 48 of the US (Figure 2), and the history of ma'iinganag from the region surrounding the ceded territories provides perspective on the history of wolves within them.

Figure 2. Historic gray wolf range before European settlement (U.S.F.W.S, 2009).

Prior to European contact, ma'iinganag ranged not only throughout the entire 1837 and 1842 ceded territories, but the entire area that would come to make up the states of Minnesota, Wisconsin, and

Michigan. However, wolves were heavily persecuted by European settlers who generally viewed them as threats to livestock, abundant populations of wild game, and humans. In Wisconsin, intensive efforts to eradicate wolves under nearly a century (1865-1957) of state-funded bounty programs ultimately met their goal, and by 1959 wolves were extirpated from the state for the first time since they originally inhabited the landscape (Theil, 1993). Similar efforts in Michigan yielded similar results, although it is thought that a very small numbers of wolves – measurable by a single digit – may have persisted in remote areas of the 1842 ceded territory in the Upper Peninsula (Michigan Wolf Management Plan, 2008).

In Minnesota, wolves were also heavily persecuted and were considered eliminated from most of the state, including all of the 1837 ceded territory, by the early 1950s (Minnesota Wolf Management Plan, 2001). However, remote areas in northern and northeastern Minnesota provided a bit of a haven for wolves, and a modest population maintained itself there – the only place in the lower 48 states where wolves were not eradicated by human persecution. The Minnesota population, which remained contiguous with wolves in Ontario, is thought to have bottomed out at roughly 350-700 animals in the mid-1960s.

Recovery

After the implementation of the federal Endangered Species Act (ESA) in 1973, the remnant Minnesota population began to increase, likely due to an increasing deer herd as well as ESA protection (Minnesota Wolf Management Plan, 2001).

While lone wolves likely occasionally dispersed through the 1837 Minnesota ceded territory after they were eradicated from the area, it is not clear exactly when packs became reestablished there. A wolf population survey conducted in 1988-89 documented range expansion toward the ceded territory compared to a previous survey conducted in 1978-79, but it was not until a 1997-98 survey was completed that some northern portions of the Minnesota 1837 ceded were considered wolf range. Range in the state has continued to expand; by the spring of 2018, about 3 quarters of the 1837 ceded territory in Minnesota was considered “wolf range,” although only about half of that area was believed to be occupied by wolf packs (John Erb, personal communication). The state is expected to make its next effort to estimate range over the winter of 2022-2023.

More intensive monitoring in the state of Wisconsin provides a more precise picture of ma’iingan recovery in that state. In the winter of 1974-75, after being absent from the state for a decade and a half, a pack was discovered near the Minnesota/Wisconsin border south of Duluth/Superior, near the boundary between the 1837 and 1842 ceded territories. By 1980, the Wisconsin population had grown to include 4 packs in the same general region, while a single pack (of uncertain origin) was discovered in Lincoln County, over 125 miles to the southeast (Thiel, 1993; Wydeven et al. 1995). All five of these packs were located within the 1837 or 1842 ceded territories.

Over the 1980s and early 1990s, these few ma’iingan packs did little but maintain themselves numerically, but they may have helped a new cohort of wolves to become established in the western Upper Peninsula (UP) of Michigan, in the 1842 ceded territory. It is thought that wolves may have also entered the UP from the east, making winter immigrations across the ice from Ontario, and entered the 1836 ceded territory (Jensen et al. 1986). The first contemporary documentation of breeding in Michigan occurred 1989, when a single pair was confirmed in the 1842 ceded territory in north Dickinson County in the central UP (Beyer et al., 2009).

From 1970 to 2004, the Minnesota wolf population displayed marked growth, reaching a level of approximately 3000 animals by the end of this period. Most of this population growth was north of the 1837 ceded territory, although a modest number of wolves had become established in the northern portions of the Minnesota 1837 ceded territory by 1997-98. It is noteworthy that the growth in Minnesota occurred despite an active lethal depredation control program which removed an average of 140 wolves from the population annually from 1992 to 2004 (Ruid et al., 2009). (Lethal control was legal in Minnesota because the Minnesota population was classified as Threatened rather than Endangered under the Endangered Species Act; it has primarily only been legal in Wisconsin and Michigan during periods of delisting, such as from 2012-2014, because wolves in those states have been listed as endangered while under the Act's protection.)

Since 2004, the Minnesota population displayed some years with substantial decline, followed by some recovery in the most recent years. The lowest estimates, from 2013-2016, seem to be associated with both years of relatively low deer abundance (resulting from intentional MnDNR management actions), and the 3-year (2012-2014) period of delisting, during which recreational killing occurred. Over the past four years for which estimates are available (2017-2020), the population has been very stable, ranging from 2,655 to 2,856 wolves, estimates which are not statistically different.

A Note on Contemporary Population Data:

Recent wolf population data has been gathered and summarized at the state level. Each of the 3 states in the ceded territory uses similar but unique methodologies to estimate wolf populations, typically incorporating radio collar data, direct observations, and track surveys. Techniques now used in all 3 states estimate the population level in late winter/early spring, when it is at its lowest point in the annual cycle.

Currently, each state estimates the total wolf population within its borders. However, until 2007 in Michigan and 2021 in Wisconsin, those states attempted to census the wolf population, generating a minimum population count, as opposed to a total population estimate. As a result, population figures made after the change in methodology are not directly comparable with those made before. More detailed descriptions of state monitoring methodologies can be found in the respective state management plans.

The growth in the Minnesota population over time seemed to initiate marked population growth in Wisconsin and Michigan, particularly within the ceded territories, beginning in the mid-1990s. The recovery in Wisconsin occurred in concert with the reaffirmation of off-reservation treaty rights in the state (David, 2009). After displaying little population growth in the 1980's (the Wisconsin population only grew from 25 individuals in 1980 to 31 in 1989), the growth in the 1990's resulted in the Wisconsin wolf population expanding to approximately 250 animals by the end of the century, with most of these animals being found in the ceded territory. Appreciable annual growth continued for more than another decade, with the population reaching approximately 850 animals in the spring of 2012 (WDNR data).

Growth in the Wisconsin ma'iingan population was interrupted in 2013 and 2014 after wolves in the Western Great Lakes region were federally delisted in the spring of 2012. Delisting resulted in two substantial new forms of human-induced mortality in Wisconsin: lethal depredation control and recreational killing (see Mortality section). The latter was forced upon the state when the Republican-controlled legislature quickly passed a law requiring a recreational hunting and trapping season whenever wolves were not on the federal or state Endangered Species lists (2011 Wisconsin Act 169).

The state wolf population began to rebound after the state reduced the harvest quota for the 2014 season, and growth continued when a successful legal challenge to the 2012 delisting returned Endangered Species Act protections to ma'iingan in the western Great Lakes region in December 2014. The Wisconsin population continued to grow until 2017, then showed little change for 2 years before again showing an increase in 2020.

In 2021, the state ceased conducting an annual minimum count of wolves and began estimating the population solely by the use an occupancy model (OM). The OM had been tested over the 3 previous years (2018-2020); during this period the OM generated a population estimate that was about 14.5% higher than the annual minimum count produced. The spring 2021 population estimate, state-wide, was 1,126 wolves, with a 95% credible interval of 937-1,364. This figure included about 41 wolves living primarily within reservation boundaries. About 84% of the Wisconsin population lived within the ceded territories. This is the most recent population estimate available at the time this document was written. However, this figure applied to the population prior to a devastating sport season that took place in February of 2021 (see Mortality section). While uncertain at this time, it has been estimated that that season, coupled with other forms of mortality and reduced recruitment resulting from the February season, could have reduced the population by approximately 30% (Treves et al. 2021).

Ma'iingan population growth in Michigan followed a similar numeric trajectory as was seen in Wisconsin, with Michigan population estimates frequently lagging Wisconsin numbers by about a year. However, the Michigan population, all located in the UP, stopped growing in 2011. Since 2011, the MiDNR has generally made population estimates every other year. Since 2011, the estimated population has ranged from 618 to 695, and averaged 653 ma'iinganag. The Michigan wolf population did not appear to be appreciably affected by the 2012-2014 delisting period (see Mortality section) due to very low levels of lethal depredation control, and minimal take during a 2013 harvest season limited to areas with above-average livestock depredation levels. (While the northern Lower Peninsula of Michigan has appreciable areas of suitable habitat, to date ma'iinganag have not successfully established a sustaining population in that area.)

Approximate Three-State, And Ceded Territory Population Estimate

While the Minnesota wolf population is the largest of the 3 states, the portion of the 1837 ceded territory which extends into what is now Minnesota is south of the state's primary wolf range, and thus this state contributes the fewest wolves to the ceded territory count. Of the estimated 2,696 ma'iinganag estimated to inhabit the state in spring of 2020, about 173 are estimated to live within the 1837 ceded territory, based on the portion of the area occupied by packs (about 4,623 km2) and average territory size and pack size that year (J. Erb, personal communication).

Unlike Minnesota, most Wisconsin's wolves are found in the ceded territory, with the primary exception being those ma'iinganag that have re-colonized the central sands portion of the state. Of the state-wide population estimate for spring 2021 (before the February hunt) of 1,126, about 952 resided within the ceded territory, including about 41 wolves living primarily within tribal reservations.

Wolves have been documented in every county in Michigan's UP (where the entire Michigan population currently resides (exclusive of wolves on Isle Royale)), but wolf density currently is about 1.8 times higher in the 1842 ceded territory than in the 1836 UP ceded territory. As a result, about 64% of the Michigan population is in the 1842 ceded territory (B. Roell, personal communication). This suggests that of the spring 2020 population estimate of 695 wolves, about 445 reside in the 1842 ceded territory.

Thus, prior to Wisconsin's February 2021 recreational killing season, the total ma'iingan population in the 3 states likely numbered about 4,500 animals, with over a third of this figure (about 1,570) residing in the 1837 or 1842 ceded territories. While many concerns about the future health of the ma'iingan population remain, there has nevertheless been a remarkable recovery of ma'iinganag since 1970, when the 1837 and 1842 ceded territories were devoid of wolves. Today, Ojibwe people may potentially encounter their brother in nearly any part of the 1837 and 1842 ceded territories, and ma'iingan and the Ojibwe may again fulfill their obligations to each other, if the population is properly stewarded for the generations yet to come (Figure 3).

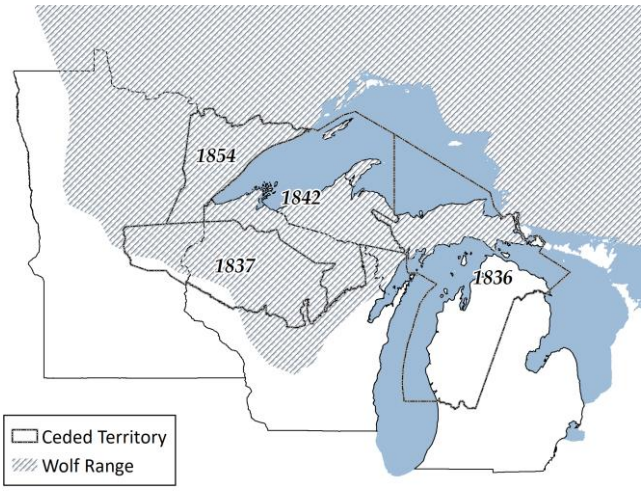

Figure 3. Current range of the gray wolf in the ceded territories of Minnesota, Wisconsin, and Michigan (IUCN, 2022).

Ma'iingan's Natural Level: The Ceded Territories Potential Biological Carrying Capacity

One measure of the health of the ma'iingan population is how close the population is relative to its "natural level" on the landscape. While this level is not a specific, fixed number – the number of any species will vary over time with changes in weather, diseases, food availability and other factors – wolf populations that are not subject to hunting tend to show only modest year-to-year variation once this level is reached. This level is referred to in ecological science as the biological carrying capacity, or "K." This level is also important because the benefits (often call "ecological services" in scientific literature) which ma'iinganag provide are maximized when wolves reach and maintain this level.

It can be difficult to determine K for any species, especially one that is introduced to a new area or may still be recovering from earlier extirpation. Models have been developed and used to predict K for ma'iinganag in particular areas, but models inherently include assumptions that may or may not prove sound. Early estimates of K for ma'iingan in Wisconsin, for example, estimated K at about 500 animals, or less than the half of the recent population estimate for the state, due to faulty assumptions about the suitability of habitat.

Determining K for wolves is complicated by the fact that human-induced mortality – particularly legal and illegal killing – can greatly influence the number of wolves on the landscape. While models can be improved over time, and biologists certainly have learned much over the past 20 years that have helped refine models used to estimate K, the truest determination of K would come from minimizing human-induced mortality and allowing ma'iinganag to determine their own level on the land.

Because of their highly territorial behavior and normally limited prey availability, wolf populations at K are typically at very modest levels compared to most other species. In Wisconsin, for example, the black bear population is more than 20x higher than the peak estimates of the wolf population. In addition, wolf populations do not normally appreciable exceed K for even short periods of time (unlike some species). When human-induced mortality is low, and wolves approach K, interspecific (wolf-on-wolf)

mortality often becomes the predominate cause of death in ma'iingan populations, serving to maintain the population at a level appropriate for the environment.

The relative stabilization of the Minnesota wolf population – which has not been hunted since 2014 - suggests that K has been reached in that state and is in the range of 2500-3000 animals. (This assumes that current levels of human-induced mortality, primarily poaching and lethal depredation control, are not significant enough to be maintaining the population below K.) The actual number of wolves on the landscape currently appears to vary from year-to-year primarily in response to changes in the deer population which result from human management or weather impacts.

Similarly, the plateau in population estimates for the Michigan's UP suggest that the wolves may have reached K there as well. This population has not been subject to appreciable levels of sport harvest since recovery, and relatively few animals are taken under lethal depredation control each year. However, the level the population has plateaued at is well below the level of K predicted by some models. A habitat suitability model developed by Mladenoff et al. (2009) developed for the 3-state region suggests that Wisconsin and the UP have about half (52% and 51%, respectively) as much quality wolf habitat (defined as the area with a greater than 51% probability of being occupied) as Minnesota, so K in these states is likely considerably smaller than in Minnesota. While this figure alone is not sufficient to make an estimate of K, the disparity between the population levels in Michigan versus the other 2 states has some biologists concerned that illegal kill in the state may be high enough to impact current population levels. On the other hand, it may be that heavier average snow fall levels in the UP make the area less suitable for both deer and wolves.

While the rate of population growth in Wisconsin appeared to be slowing prior to the February 2021 season, the population has not yet clearly plateaued. Stenglein et al. (2015) estimated K for Wisconsin to be 1242 wolves, a level only about 10% higher than the figure estimated by the WDNR's occupancy model for the population prior to the February 2021 recreational season. That season, and possible future seasons in the state, could prevent wolves from establishing their own level on the landscape.

In short, while the precise level of K in the ceded territory remains uncertain, it appears that the wolf populations in all 3 states of the ceded territory may have been approaching K in the spring of 2021 before Wisconsin had its February season.

MA'IINGAN BIOLOGY AND ECOLOGY: A SUMMARY

A full summary of ma'iingan biology is beyond the scope of this document. However, a basic summary of biological characteristics can be informative for some readers, while providing biological support for certain stewardship actions or policy positions.

Individual Ma'iingan

Wolves are the largest member of the Canid or dog family, which also includes (in the treaty territories) coyotes and foxes, as well as domesticated dogs. They can be differentiated from coyotes by several characteristics including their calls, height, and weight (coyotes weigh about half as much as wolves), and foot size. Facial features also differ, with wolf ears being shorter and rounder than the longer and more pointed ears of a coyote; wolves also have a broader face and snout, which are narrower in coyotes. Nevertheless, with the brief glimpses often gained under field conditions it can be difficult to identify between the two without physical evidence such at tracks. Coyote tracks are typically less than 3 inches long, wolf more than 4 (including nails). However, it can be difficult to differentiate between the tracks of large dogs and wolves.

The table below lists weights for adult wolves in each of the three states in the treaty territory as reported in respective state management plans. In comparison, average weights reported for German Shepherds are 66-88 pounds for males and 49-71 pounds for females.

Table 1. Weights of adult wolves in the Great Lakes region.

Gender	Minnesota	Wisconsin	Michigan*
Males	70-110 lbs	57-102 lbs (ave: 77 lbs)	Ave: 87 lbs
Females	50-85 lbs	46-75 lbs (ave: 62 lbs)	Ave: 76 lbs

* Michigan also reported a weight range of 58-112 pounds, both sexes combined.

Life Span

While wolves in zoos have lived up to 20 years, wild ma'iinganag have challenging lives, and generally are not long-lived. The International Wolf Center (Ely MN) website reports that "many pups don't make it through the first winter of their lives. Those that survive the first two years have a pretty good chance of living another two to four years if they can avoid fatal injury and if they can get enough to eat. Some wild wolves do live to be 9 or 10, and there are verified records of a few living into their early teens."

Social Structure: Life in the Pack

Ma'iinganag are highly social animals, and most wolves spend their lives living in packs, which are analogous to family groups. Pack size can range from a mated pair to a dozen or more animals, but averages about 4.1 individuals in Wisconsin, 4.7 in Michigan and 5.1 in Minnesota (see respective state wolf plans). Packs typically consist of the breeding pair (previously often referred to as the Alpha pair), surviving offspring from the previous year, and the current year's pups, but older offspring or unrelated animals may also be members of a pack. While these reported pack sizes are smaller than many in the public expect, it is in part because of when and how wolves are usually counted: population estimates (including pack size) are generally made in the late winter/early spring, when both packs and the population are typically at their lowest. In addition, a breeding pair of animals is considered a pack, even before pups are born. At other times of the year, and under certain circumstances, wolf packs can be much larger; the Druid Peak pack in Yellowstone National Park once included more than 30 individuals, but large packs are fairly rare in the treaty territories and may split into 2 packs when they do occur. Pack sizes in the treaty territories may also be smaller than in some other areas because white-tailed deer are the primary prey in this area; pack sizes tend to be higher in areas where the primary prey specie is larger, such as moose, elk, or bison.

Wolves in a pack – especially yearlings approaching their second birthday – often face a choice to either remain in the pack in hopes of someday achieving breeding status or dispersing out in hopes of finding a mate and vacant (or assumable) territory as they approach sexual maturity. It is difficult to estimate the number of "lone wolves" that may exist in an area at any time, and the number undoubtedly varies with time of year, availability of vacant habitat and other factors. Estimates tend to fall in the 10-15% range, (Fuller, et al., 2003). However, these estimates are often surmised, or based limited data, and the percentage may be lower when population data is typically gathered than at other times of the year. With the development of GPS tracking collars, some lone wolves have been documented making

remarkable journeys – sometimes of hundreds and even thousands of travel miles, in efforts to find a suitable partner and place to settle. It Is quite possible that a single lone wolf could be counted in multiple survey areas as it moves across the land.

Territoriality

While ma'iinganag are highly social within their pack, they are also highly territorial beings, and will strongly defend their pack's territory from other wolves. Ma'iingan territories in the 1837 and 1842 Ceded Territories average about 65-70 square miles in size but may vary over time in response to changes in the availability of vulnerable prey and other factors. Since wolves will usually attempt to exclude other wolves from their territory, wolf population growth becomes self-limiting as suitable habitat is occupied. In areas where human-induced mortality is low and wolf populations are well established, wolf-on-wolf mortality is often a leading cause of death. As a result, wolf populations never reach very high densities compared to most species of animals.

Reproduction

Growth in wolf populations is highly influenced by several factors, including their social structure. Wolves are sexually mature at 22 months, but in most cases reproduction within a pack is limited to a single breeding pair. In the 1837 and 1842 ceded territories, breeding generally takes place between late January and early March; with a gestation period lasting 60-63 days, most pups are born in April. Litter size is typically 4-8. Pups are kept at the den site for 6-8 weeks, but by mid-June are moved to the first rendezvous site, an area they occupy while adults are seeking food. Over the summer, 2-3 rendezvous sites will be used. By September/October, the pups have grown enough to begin traveling with adults, and the pack becomes more nomadic over its territory. Pup survival is highly variable, but on average only about 3 out of 10 pups will survive their first year. In addition, various factors, including food scarcity and hunting seasons, can result in a pack failing to produce pups at all.

Diet

Ma'iinganag have primarily a carnivorous diet, eating many of the same beings that Ojibwe people eat. Within the 1837 and 1842 treaty territories, the most important animal in the diet is the white-tailed deer, followed by beaver. Studies suggest that a wolf consumes about 16-19 deer a year, and perhaps 10-25 beaver (varying by location, season and even the hunting practices of individual wolves; one wolf in Voyageurs National Park killed and ate 36 beavers in a single year). Wolves also eat smaller animals such as snow-shoe hares, birds and even rodents. Interestingly, we are still learning more about ma'iingan's diet; recently, wolves in northern Minnesota have been documented catching fish, an activity not previously documented on inland waterways. They have also been shown to seasonally consume significant amounts of blueberries, both for their own nutrition, and - by gorging on them and regurgitating them back at the rendezvous site - for the pups (Homkes et al., 2020).

Ma'iingan's Relationship with Prey: White-Tailed Deer

> *"Our Reservation home has a healthy deer herd and healthy wolves."*
>
> *Chairman Mike Wiggens Jr., Bad River*

Because ma'iingan in the ceded territories feed primarily on deer, many people contend that ma'iinganag must reduce the deer population, and so wolves should be killed so there can be more deer. However, neither traditional Ojibwe nor western science support this contention. Wolves and deer have co-evolved over countless generations, and healthy deer are well equipped to avoid being preyed upon. Unlike human deer hunters, wolves select old,

weak, injured, or diseased individuals, contributing to the long-term health of the deer herd. The numeric impact on the deer herd is also lessened in other ways. For example, wolves will feed on deer killed by cars, or killed but not retrieved by hunters. There also are probably at least two forms of compensation for some of the take that does occur: wolves will reduce the number of coyotes in an area, and thus fewer deer are taken by that being in areas occupied by wolves, and a recent study also found that wolves alter deer behavior, reducing the time they spend on roads. This not only saves humans' money by reducing the number of deer/vehicle accidents which occur (estimated at 63x the costs of verified wolf depredations on livestock), but it reduces the number of deer that are killed by cars (Raynor et al., 2021).

> *"Where there is the ma'iingan, the Anishinaabe know that there will be good hunting."*
>
> *Marvin DeFoe, Red Cliff*

Wolves (and other predators) likely play an important role limiting the spread and prevalence of infectious diseases in deer and elk, including Chronic Wasting Disease (Wild et al., 2011, Brandell et al. 2022). It may take 1.5-2.5 years (or longer) for an infected deer to reach the clinical stage of infection, where humans would be able to observe physical changes in the deer's appearance and behavior. Ma'iingan's sense of smell is extraordinary; by having 50x as many olfactory receptors than humans, the accuracy of their sense of smell is 10,000 – 100,000x better than our own (Vucetich, 2021). As a result, they likely can detect infected animals long before humans observe the behavior changes brought about by the disease. A study of cougars suggested that they select for CWD infected prey (Krumm et al., 2009), and another study found that when captive cougars were fed meat spiked with CWD prions, more than 96% of the prions were destroyed by passing through cougars' digestive system (Baune et al., 2021). While these findings have not yet been confirmed in wolves, both are likely to hold true; in fact, ma'iingan are believed to be more selective for diseased (and injured or weak) animals than cougars because wolves predominantly track, chase, and select ungulate prey, rather than ambush them as cougars do.

In addition, the deer population is impacted by many other factors, including winter severity, habitat quality, human harvest (which is far greater), losses to other predators like bear, coyotes and even bobcats (on fawns), vehicle collisions, and disease (Sitar, K and B. Roell, 2021). Losses to ma'iinganag alone simply are not great enough to be a primary factor determining the number of deer on the landscape. Generally, the number of deer on the landscape greatly influences the number of wolves an area can support, rather than wolves determining the number of deer.

However, wolves will affect the distribution and behavior of deer at a very local level. While many sport hunters consistently push for very high deer numbers, over-abundant deer populations can have many negative ecological and social impacts, including crop damage, car accidents, and impacts on wild plant communities (Callan et al., 2013; Sabo et al. 2017). One result of this is that plant communities tend to be more diverse and have a greater abundance of the species which deer prefer where wolves are present. Some of the plants which benefit from this have important uses to tribal members as food or medicines; others are important for the health and abundance of other animal beings.

>
> *Conrad St. John, St. Croix Tribe*

Ma'iingan's Relationship with Prey: Elk

Both ma'iinganag and omashkoozoog are beings that were native to and then eliminated from the ceded territories. These beings have only relatively recently reestablished populations in portions of their former range within the ceded territories, and time will tell how their relationship will evolve.

There are many similarities in the ecological relationship between ma'iinganag and waawaashkeshiwag and the relationship between ma'iinganag and omashkoozoog. As another member of the deer family, elk are a prey species for wolves. However, elk are much larger than deer, which may serve to their advantage. Their longer legs can allow them to travel more efficiently through deeper snow than deer, meaning they may be able to avoid predation under certain snow conditions. This advantage only lasts until the deep snow develops a hard crust, switching the advantage to being more in favor of wolves.

Omashkooz (elk) were once abundant throughout much of the western Great Lakes region, including portions of the 1837 and 1842 ceded territories. However, as European settlement expanded westward, elk in the ceded territories were extirpated by the mid-1800s due to unregulated hunting and loss of habitat. In 1995, an elk reintroduction program was started when 25 elk were released near Clam Lake, WI. Additional elk were translocated to the Clam Lake herd between 2015 and 2019 to increase genetic diversity, increase the number of breeding age females, and to expand the distribution of elk throughout the designated elk range. An additional elk reintroduction site was established in the central part of Wisconsin (outside of the ceded territory) in 2015. In 2018, the Clam Lake elk herd had grown to over 200 elk, which, by state rule, triggered the first managed, conservative, bull-only elk hunt. By 2021, the post-calving population estimate was approximately 332 (296-365, 95% CI) elk. This remains the only elk population in the ceded territory; the population goal for omashkoozoog in the Clam Lake elk range is currently 1,400 elk. One of the current primary objectives for the elk herd is to maximize herd growth to reach that population goal.

Over the duration of the elk reintroduction program, the elk within the herd experienced many causes of mortality. Since many of these elk were fitted with radio tracking collars, biologists were able to investigate and determine the causes of mortality of some, but not all of the elk that died. Of those sources of mortality that were investigated, biologists confirmed that wolf predation accounted for 122 of 377 known mortalities between 1995 and 2020, or about 5 elk per year. Additional sources of mortality included vehicle car collisions, bacterial diseases, bear predation (primarily of calves), legal and illegal harvest, and drowning, among others. Despite wolf predation being the primary source of confirmed mortality in the Clam Lake elk herd, the rate of wolf predation does not appear to be having a significant impact on the growth of the herd. Like deer, the growth of the elk herd can be influenced by several factors, such as winter severity, habitat, and hunter intensity.

Like deer, elk are also susceptible to chronic wasting disease (CWD), but as of early 2022, no wild elk in Wisconsin have tested positive for the disease. The northern and central herds are in areas adjacent to where CWD has been detected in wild deer, so the risk to wild elk is an ongoing concern. As was described in the ma'iingan-deer section above, large predators like ma'iinganag may play an important role in mitigating the spread and/or prevalence of CWD on the landscape. Efforts are currently underway to design and implement scientific field research on the wolf-prey-CWD relationship.

Ma'iingan's Relationship with Prey: Moose

The only established moose population in the 1837/1842 ceded territories can be found near the northeast edge of the 1842 ceded territory, primarily in what is now part of Marquette, Baraga, and Iron counties in Michigan. This population, while small, has demonstrated slow but overall positive growth since it was re-established by air-lifting moose in from Ontario in 1985 and 1987. The most recent survey of this population, conducted in 2019, estimated the population at a little over 500 moose. (A smaller population, not surveyed but believed to number less than 100 animals, also exists further east in the UP in the 1836 ceded territory, in the vicinity of the Seney Wildlife Area.)

As with many other beings, ma'iingan's relationship with moose likely varies depending on the location, habitat, and a host of other factors, and one may need to use caution on applying findings from one area to another. For example, fascinating insights have been gained from one of the longest predator/prey studies in history, which has focused on moose/wolf relationships on Isle Royale, but the unique conditions which exist on the island may have limited application on mainland populations of either species.

Unlike with white-tailed deer, there has been relatively little public concern expressed about possible negative effects of ma'iinganag on the Michigan moose population. This may be because the population has been slowly building over time - while moose populations in many areas on the southern edge of their range have been in decline - or because hunters hold less interest because this population has never been subject to a harvest season.

While some people blame wolves for moose population declines in other areas, it appears that other factors associated with habitat changes and climate change may be underlying moose decline, as moose have also declined in areas without wolves. High populations of white-tailed deer pose another threat, as a brain worm that has little impact on deer can be fatal in moose. A recent study in northeast Minnesota found that wolves may mitigate this problem to a degree, by acting to separate deer and moose populations, reducing transmission (Oliveira-Santos et al., 2021).

Ma'iingan's Relationship with Prey: Beavers

Ma'iingan's relationship with beavers is complex, and likely varies markedly in different landscapes and with different beaver densities and even the behavior of individual wolves. Beavers are likely the second-most important food for wolves in the ceded territories, but the impact wolves have on beaver populations are not well understood here. In Yellowstone, where beavers were quite rare, wolf reintroduction appeared to increase beaver numbers by triggering a trophic cascade – a "discovery" consistent with TEK teachings about the interconnectedness of all life. In this instance, it was brought about by wolves impacting elk feeding behavior, which encouraged tree regeneration in river valleys, which provided habitat for beaver. In Voyageurs National Park, where beavers are abundant, beaver seem to be an important spring and summer food source but appear to have little impact on beaver population levels (Gable et al., 2020). And on Isle Royale, an increase in beaver populations seemed to be associated with a period of low wolf numbers. Collectively, these findings suggest caution when assuming the impacts of ma'iingan on beaver in particular areas.

However, all these studies also suggest that wolves can indirectly impact hydrology in an area by impacting beaver presence and activity, as well as impacting plant communities which may in turn affect hydrology. Gable et al. (2020) summarized it by stating "By affecting where and when beavers engineer

ecosystems, wolves alter all of the ecological processes (e.g., water storage, nutrient cycling, and forest succession) that occur due to beaver-created impoundments," another reminder of complexity and interconnectedness of natural communities.

Ma'iingan's Relationship with Prey: Hares and Small Rodents

While wolves will eat many different animals at times, the proportion of their annual diet that does not consist of deer and beaver is relatively small, and given the relatively small number of wolves on the landscape even when their population is at carrying capacity, the direct impacts of ma'iinganag on the populations of other prey species is likely negligible.

However, as a top-level predator, wolves may affect rodents - and many plant and animal species - indirectly, through other examples of trophic cascades The indirect impacts of wolves on plants, by altering deer behavior, is discussed above. A similar chain is thought to exist regarding wolves, other Canids, rodents, and ticks. Computer modeling suggests this cascade work as follows: Wolves reduce the abundance of coyotes in an area, which allows the population of fox to increase. Fox are the most efficient predators of small rodents which can be important transmitters of ticks, and thus tick-borne diseases (Levi et al., 2012). Thus, healthy wolf populations may ultimately reduce human exposure to tick-borne diseases such as Lyme disease, anaplasmosis, and ehrlichiosis, all of which have a significant presence in the ceded territory.

Ma'iingan's Relationship with Scavengers, Including Ravens

Wolves often are not able to completely consume their larger prey in a single feeding event, and thus many species have been observed utilizing the carcasses of wolf-killed animals, including ravens, eagles, bears, coyotes, fox, and many others. It has been noted that these "subsidies" from wolves are more important to scavenger populations than the remains left by hunters because they are available year-round (Wilmers et al., 2003). In Yellowstone, this provisioning was found to help stabilize the raven population by providing a regular food supply, regardless of winter severity (Walker et al., 2018). The hair left behind at kill sites can be used by small mammals and birds for nest building (Seward et al. 2004). If the prey was a mature male elk or deer, the antlers can provide minerals and nutrients for porcupines, squirrels, rabbits, and various other small mammals. Decomposers, such as invertebrates, bacteria, and fungi can also benefit from the remains of the carcass. Eventually, when the remains of a wolf-killed elk, deer, or moose fully decompose, the various nutrients and minerals enter the soil, which can influence tree reproduction. These biogeochemical "hotspots" in the herbaceous layer of the forest at wolf prey carcass sites may also influence plant biodiversity (Bump et al. 2009). This, in turn, can be one additional factor contributing to healthier forest ecosystems, sustaining life for all beings within the forest. While the subsidy provided to scavengers may be less in the ceded territories than in areas where wolf prey species are commonly larger (like elk), there is little doubt many species in the ceded territories besides humans benefit from having wolves in the ecosystem.

Naturalists and wildlife watchers have recorded many observations of wolf and raven interactions. An unattributed "Native American saying" is that the wolf acts as the raven's tooth and the raven as the wolf's eye. There are many reported observations of ravens attracting wolves to animal carcasses through loud calling; the ravens later benefit by having wolves open the carcass, making parts available for the ravens to scavenge. There are also reports of ravens playing with wolf pups, including playing "tug of war" with them using sticks.

John Vucetich (2021) has even hypothesized that ravens may be part of the reason that wolves hunt in packs, suggesting that packs allow wolves to lose less of the kill to ravens, as more of the kill can be immediately consumed.

These ecological influences of the wolf-prey relationship illustrate not only the importance of large predators like ma'iingan, but also emphasizes the interconnectivity of everything.

Mortality

Natural mortality in wolves can take many forms, including disease, starvation, injury/accident related, and predation, especially intra-specific (wolf on wolf) predation. Human-induced mortality also takes several forms. Non-intentional forms include vehicle accidents, wolves accidentally shot when mistaken for legal game, and wounding loss during recreational killing seasons. Intentional human mortality includes government-authorized killing such as hunting and trapping seasons, lethal control in response to livestock depredations (and rarely pet depredation or human safety concerns), and poaching. Mortality levels can vary significantly from year-to-year. Mortality rates can leap when wolves are delisted from federal protection, particularly in Wisconsin, where a state law requires a recreational killing season to take place (with its associated wounding loss), and lethal depredation control also occurs when wolves' federal status changes from Endangered to unlisted. In addition, research suggests that illegal killing of wolves increases when federal protections are removed (Santiago-Ávila et al., 2020).

While natal year mortality is typically high at about 70%, mortality for wolves 1-year-old and older averages about 35% in stable populations and can be considerably less in populations that are growing, particularly when protected from hunting, trapping and depredation removal. This relatively modest rate of adult mortality is significant because it limits how much the population can compensate for other sources of mortality, including depredation control and recreational harvest.

In Wisconsin, where more than half of the ceded territory wolves live, mortality from illegal and accidental kill is thought to be in the range of 10-19% of the adult population (Stenglein and Van Deelen, personal communication). Estimates of illegal kill in the Minnesota or Michigan are not available, but some biologists are concerned that the relatively low level the Michigan ma'iingan population has plateaued at suggests illegal kill may be even higher in that state.

Lethal depredation control has been on-going in Minnesota, where ma'iingan have always been listed as Threatened, rather than Endangered, when ESA protections are in place. It is also important to note that while lethal removal of depredating animals has been greatest in Wisconsin and Michigan during the periods of delisting which occurred from 2012-2014 and again since January of 2021, lower levels of lethal depredation control also occurred during many other years under special rules (Table 1).

Recreational wolf killing occurred in Minnesota from 2012-2014; in Wisconsin from 2012-2014 and in 2021, and in Michigan only in 2013. Table 2 summarizes the number of wolves killed under state-authorized take in each state since 2010 and shows the great differences between states. Of course, the biological impact of recreational harvest varies not only with the proportion of the population that is killed, but the sex and age of the animals killed. Timing of the killing is also important. For example, when one of the breeding members of a pack is killed in November or December, there may be an opportunity for another animal to fulfill that role before the breeding season arrives in February. Wisconsin's February 2021 wolf season was not comparable to any other wolf season on record by occurring entirely within the middle of ma'iingan's breeding season. There is little doubt that the impact

on the population was greater than just the number of animals killed would suggest, but no post-kill population estimate was available at the time this document was written.

Table 2. Number of ma'iingan killed, by state, through lethal control or recreational killings, 2010 -2021. Number killed is reported by calendar year for lethal control; recreational kill is reported by the year which the killing season began or would have normally began (see footnote). Lethal control primarily consists of killing in response to livestock depredations, but also includes small numbers of wolves killed in response to pet depredations or human safety concerns. Most lethal control is done by USDA – APHIS Wildlife Services staff, but some was conducted by state representatives, or landowners during periods of delisting. Data compiled from various sources including USDA-Wildlife Services Reports and annual state DNR harvest season reports. MI data provided by B. Roell. MN data does not include take by private landowners.

State	Kill Type	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020	2021	Total

[a] Includes take by USDA-Wildlife Services and state contracted trappers.

[b] Although this killing occurred in February of 2021, the season which would have normally began in 2020 and is shown as such here to make clear it occurred before the 2021 depredation season.

Diseases and Parasites

Ma'iinganag are known to susceptible to a fairly large number of diseases and parasites, including rabies, canine distemper, canine parvovirus, mange, and dozens of different round worms, tape worms, flukes, or other parasites. However, relatively little is understood about the impacts that each may have on wolf populations and learning more about these impacts is challenging. The impact of each likely varies with factors such as the age, condition, and genetics of the infected wolf, as well as previous exposure the population may have had with the negative agent. In addition, since individual wolves often may be subject to more than one disease or parasite at a time, individual effects may be hard to discern, and cumulative effects may be greater than the sum of individual impacts. Although the paper is now nearly 30 years old, one of the most comprehensive summaries of known infectious and parasitic diseases can be found in Brand et al. (1995). In small, isolated, or recently introduced populations, diseases can sometimes have appreciable impacts on wolf populations. An outbreak of distemper in Yellowstone was associated with a 30% decline in the population in 2005 (Almberg et al.,2016), and the introduction of parvovirus to Isle Royale by visitors by dogs resulted caused a crash in the ma'iingan population there (Wilmers et al. 2006), with the population declining from 51 to 14 animals in 2 years.

LEGAL BACKGROUND

To a degree far greater than for most species, ma'iingan's relationship with people has been interwoven with human law. For the Ojibwe, it began with the original treaties - the "Supreme Law of the Land" discussed above - that defined some of the tribes' relationship with, and responsibility towards, ma'iingan. The relationship between non-tribal members and wolves in the US has also frequently been a matter of law, particularly the Endangered Species Act (ESA). There is also some mention of wolves in the court cases associated with re-affirmation of off-reservation treaty rights, but it is quite limited. Finally, legal responsibilities are also woven into the federal government's treaty obligations and trust responsibility to the tribes. Each of these legal constructs not only affects wolves directly but adds complexity to ma'iingan stewardship in the ceded territories.

It is important to note that since ma'iingan is the brother to the Ojibwe, they are considered tribal members. In this understanding, treaty rights which the tribes hold are also held by ma'iingan.

Federal Laws

The most important federal law regarding wolves is the Endangered Species Act (ESA). Wolves were the first species covered by ESA protections. When the ESA was passed, the only wolves remaining in the contiguous 48 states were found in northern Minnesota. As a result, ma'iinganag in Minnesota were listed as Threatened under the Act; in the remainder of the 48 contiguous states, they were listed as Endangered. The most significant practical difference between the two statuses is that in Minnesota, wolves could be killed in response to livestock depredations, but nowhere else; recreational hunting and trapping was not allowed anywhere.

While a full review of the history of ESA protections for wolves in the ceded territory is beyond the scope of this document, it is important to consider the massive swings in state wolf "management" that have occurred when status under the ESA has changed.

In the ceded territories, for example, over the last 2 decades ma'iinganag have been either downlisted (once) or delisted (4 times), with each action eventually being reversed because of legal challenges. The most recent delisting occurred in January of 2021 and led to the disastrous February 2021 Wisconsin hunt. (Another Wisconsin season, planned for the fall of 2021, was blocked by a suit brought in state court.) That delisting was reversed in February of 2022, again reverting wolves to Threatened status in Minnesota and Endangered in Wisconsin and Michigan. Thus, the current federal status of wolves is not consistent across the 1837 and 1842 ceded territories.

The status of ma'iinganag under the ESA is often greatly influenced by their status outside of the "Western Great Lakes" (a term used by the US Fish and Wildlife Service) population. While significant recovery of wolves has occurred in northern Minnesota, northern Wisconsin and Michigan's Upper Peninsula, large areas of historic and currently suitable range in the contiguous 48 states remain unrecovered. Nevertheless, federal delistings have consistently included areas well beyond the region where recovery has actually occurred, one of the factors which has led to delisting reversals. It appears likely that swings in wolf status under the ESA will continue to occur, at least in some areas.

One major issue related to delisting is that states have often responded to them by rapidly initiating wolf seasons, often aggressive ones. As noted above, Minnesota and Wisconsin held annual seasons

during the 2012-2014 delisting period, and the Wisconsin DNR was forced to hurriedly implement the February 2021 season – despite opposition from the Department, which recognized it needed more time to adequately prepare for it – because of the state law requiring a season.

Neither Minnesota nor Michigan held seasons in 2021. Instead, both states initiated consultation with their publics and with the tribes, and both conducted social attitude surveys and began updates to their state wolf plans. These thoughtful and measured responses to the most recent delisting hopefully reflect a positive development in wolf conservation in those states.

Federal Trust Responsibility

Regardless of ma'iingan's status under the ESA, the federal government holds treaty obligations and a trust responsibility to the tribes. What this means in practice regarding ma'iingan stewardship has not been clear, and federal agencies have largely seemed unenthused about embracing this responsibility, especially on off-reservation ceded lands, during previous periods of delisting.

Recently however, there have been two encouraging developments which may suggest greater implementation of these obligations going forward.

In November of 2021, the Department of the Interior and the Department of Agriculture issued *Joint Secretarial Order No. 3403, Fulfilling the Trust Responsibility to Indian Tribes in the Stewardship of Federal Lands and Waters*. This order includes provisions regarding the development of agreements with federally recognized tribes for stewardship of federal lands and waters, including wildlife and its habitat. This order could create significant opportunities for ma'iingan stewardship in the ceded territory, primarily because of the large acreage of federal lands, especially National Forests, they contain. Because off-reservation harvesting rights are currently limited to public lands, the health of the ma'iingan population and the benefits they provide, is critical on these lands. Nevertheless, harvest from state wolf seasons is often disproportionally taken from these very lands. For example, while only 28% of the Wisconsin ceded territory is public, 80% of the February 2021 kill was reported on public land. A co-stewardship agreement to protect wolves on National Forests would not only greatly protect tribal interests but would help protect Forest Service interests in forest regeneration and maintaining biological diversity.

Precedents exist for closing federal lands in Wisconsin to wolf hunting. The Apostle Islands National Park does not allow the taking of wolves from its mainland unit, or from Sand or Long Islands, and Fort McCoy is closed to wolf hunting or trapping.

The second encouraging development occurred in January of 2022, when Assistant Secretaries for the Bureau of Indian Affairs and Fish and Wildlife and Parks sent a letter to WDNR Secretary Preston Cole recognizing the tribes' rights not only to harvest species, "but to conserve and protect them to ensure healthy populations and protect vital ecosystems that support the exercise of treaty-reserved rights." Furthermore, the letter indicated that it was the Department's view that Wisconsin must "honor the Ojibwe Tribes' reserved rights, including their right to protect rather than take wolves, as it undertakes the next round of planning for gray wolf hunts under Wisconsin State Law."

Hopefully these two actions signal greater implementation of the federal treaty obligations and trust responsibility in the future and will help secure the health of the ceded territory ma'iingan population.

Ma'iingan and the Endangered Species Act

The intersection of the Endangered Species Act and the Ojibwe world view has long highlighted significant differences behind the two respective cultures. The ESA is a non-tribal construct designed to protect beings whose populations are in serious peril, and has often being described as the "emergency room" of western wildlife management. It played a critical role in allowing wolves in the Midwest to recover and again occupy traditional lands in the ceded territory, and the tribes appreciate and are thankful for its existence.

The divergence in perspectives becomes pronounced when wolves (or other species) become delisted. The respect and concern previously given to species can appear to evaporate with the stroke of a pen, as happened in Wisconsin in February of 2021, when over 20% of the wolf population was slaughtered, in the middle of their breeding season, just weeks after being "wheeled out of the emergency room." In the tribal perspective, the relationship with wolves should always be respectful and reciprocal, and so there has often been resistance to delisting, as the protections the ESA provides ma'iinganag are seen as appropriate regardless of their biological status.

Similar perceptions towards wolves certainly exist among many in the non-tribal community – and to a clear majority of the non-tribal community in regard to another being: the Bald Eagle. Eagles are held in high cultural esteem by both cultures. The non-tribal community has expressed its desire to protect bald and golden eagles - regardless of their biological status – by creating special legislation (the Bald and Golden Eagle Protection Act) that immediately provided critical protections the moment these beings were delisted from the ESA. Similar legislation has been proposed by many environmental groups for other animals, especially large predators like wolves which hold critical environmental roles but often remain persecuted by certain portions of society. If these kinds of protections were in place for ma'iingan, opposition to delisting would likely pass.

Until the day that may happen, it is worth noting that many of the tenets outlined in this plan align closely with the protections provided species that are listed as Threatened under the ESA, including no recreational harvest, and limited, but possible, lethal control in response to livestock and pet depredations or the very rare instances of human health and safety concerns. When the health of ma'iingan populations is looked at across the contiguous 48, a national listing of wolves as Threatened appears to be a highly reasonable approach, but to date the U.S. Fish and Wildlife Service has not pursued this option.

State Management

When wolves are not under ESA protections, "management" authority shifts from the federal government to the states and tribes. Unfortunately, the impact of state actions typically dwarfs tribal impacts within the ceded territories and can even greatly affect wolves that live primarily within reservation boundaries, because regional reservations are not large enough to contain entire wolf territories.

Wolf management objectives vary by state. Providing recreational harvest opportunity is often an important concern, but this may be changing as some states' policies become more aligned with the desires of their greater constituencies, rather than just the hunting and trapping interests. Within the ceded territories, Michigan has largely avoided recreational hunting; it held only one hunt during the last two delisting periods and attempted to design that season to specifically focus take in areas with depredation issues.

Existing state management plans in the region have not specifically identified maximizing ecological function and non-hunting social benefits as goals. However, as of 2022, each of the three states is in the process of creating new or updated wolf plans. We hope the states will use this opportunity to infuse more holistic approaches to ma'iingan conservation in their plans.

> *"We are fighting for our off-reservation rights all the time."*
>
> *Chairman John Johnson Sr.*
> *Lac du Flambeau Tribe*

While the cases which reaffirmed the existence of off-reservation treaty rights were litigated in federal court, they apply most directly to the relationship between the states and the tribes. However, the cases reaffirming the treaty rights in the Wisconsin and Minnesota portions of the ceded territories provide limited guidance on the implementation of the government-to-government relationship in the realm of ma'iingan conservation. Since these cases were between the tribes and the respective states, and since wolves were under ESA protections and federal authority at the time they unfolded, the states held little legal authority regarding wolves at the time. Thus, unlike several species for which extensive management stipulations were created, no ma'iingan management/stewardship stipulation was developed and wolves were minimally addressed.

The relatively small ma'iingan population in the ceded territory at the time of the cases may have also contributed to the lack of attention they were given. In 1991 when the final judgement was entered in the *LCO v. Wisconsin* case, there were just 40 ma'iingan in Wisconsin, and likely no one anticipated the state would eventually have a 4-figure population. In 1999, when the US Supreme Court affirmed the existence of the treaty rights in the 1837 ceded territory, the Minnesota population was much more robust at about 2,500 animals, but ma'iinganag had only begun to extend their range into the Minnesota portion of the 1837 ceded territory.

The tribes' model conservation codes which were created in the Wisconsin and Minnesota cases do address ma'iinganag in two ways, however. Both codes have provisions which incorporates any plant or animal on the Federal list of Endangered or Threatened species onto the tribal list, and (with very limited exceptions) prohibits the take of these species. During periods of federal delisting, ma'iinganag can still be included on the tribal list of Threatened and Endangered species at each tribes' discretion. Lacking that action, however, both codes also include ma'iinganag among the list of "protected species,"

which no member can hunt or trap. (The code for the Wisconsin ceded territories lists "timber wolves," a common name now falling out of use; the code for the Minnesota Ceded Territory lists the now more commonly accepted "gray wolf.")

The Michigan portion of the 1842 ceded territory has not been litigated in federal court, but tribal codes have extended these protective provisions to the Michigan portion of the ceded territory as well.

Other Court Stipulations

The stipulations from the Wisconsin and Minnesota treaty cases provide additional guidance on the implementation of government-to-government consultation regarding treaty-reserved rights.

In the stipulation from the *LCO v. Wisconsin* case, it was agreed that the DNR "Wolf Committee," (and any DNR committee that is formed to address management issues of any treaty-reserved resource) shall include a recognized tribal representative as an official member. Further, it was agreed that a consensus approach would be used and that the parties would make all reasonable efforts to reach a consensus in all committees or processes outlined in the stipulation.

The Minnesota case created a *Minnesota 1837 Ceded Territory Wildlife and Plant Resources Committee* to address coordination of resource stewardship between the state and tribes. While this protocol again does not specifically address wolves because they were federally listed at the time the protocol was developed, it sets clear precedent by: assigning the committee the task of developing recommendations on harvestable surplus levels for other species, indicating that the committee shall strive to reach consensus on all issues, and laying out a detailed process for dispute resolution. The primary protocols involved should be amended to add ma'iingan to the current list of species, which includes bear, deer, turkey, and registered furbearers, to which this language applies.

Ultimately, however, it is likely that the courts will never define the full extent of the treaty right, nor every aspect of the appropriate government-to-government relationship it entails. In the end, the best outcomes for ma'iinganag will be achieved when both parties enter the relationship with respect and commitment, and focus upon the health of the ma'iingan population, rather than upon establishing relative legal authority and satisfying the minimal requirements which the court may establish.

On-Reservation Stewardship & Cooperation with Non-GLIFWC Tribes

While the focus of this plan is ceded lands outside of reservation boundaries, reservation boundaries, like state boundaries, have no significance to ma'iinganag, and some on-reservation stewardship issues inherently extend beyond the reservation border.

It is important that states also maintain appropriate government-to-government relationships with individual tribes to ensure that wolves living both on and off reservations are stewarded cooperatively.

USDA-APHIS WI has long worked cooperatively with tribes when depredations have been reported within a 6-mile buffer around the larger reservations in Wisconsin, including Red Cliff, Bad River, Lac Courte Oreilles, and Lac du Flambeau (as well as the Menominee/Stockbridge Munsee complex), allowing for joint investigation and decision making.

And while Wisconsin recognized the borders of several reservations and closed them to recreational wolf harvests, similar buffer areas have not been put in during these hunts, leaving ma'iinganag which

live primarily on tribal lands subject to harvest when they step off the reservation. This situation has been even worse in Minnesota and Michigan, which allowed hunting and trapping on non-tribal lands within reservation boundaries when recreational seasons were in place. It is incumbent upon the respective states to work with tribal government to address these issues in a cooperative manner. Failure to do so is only likely to trigger conflict.

Of course, many regional tribes that are not members of GLIFWC share many of the relationship tenets described in this plan and hold similar desires for the wolf population. We welcome opportunities to work cooperatively with these tribes to advance common concerns and promote a healthy and appropriate relationship with ma'iinganag within the ceded territory and beyond.

Finally, GLIFWC staff welcome requests from our member tribes to provide biological advice and expertise related to wolf stewardship as requested.

Livestock And Pet Depredations

Although ma'iinganag only depredate livestock on a small number and percentage of farms in the ceded territory, livestock interests often oppose ma'iingan population goals that are necessary for a healthy and biologically functional wolf population. They also have significant political clout. Depredations can also sometimes cause appreciable hardships for individual livestock raisers. Thus, it will remain important to work with the agricultural industry to gain greater support for healthy wolf populations.

Most agencies charged with responding to livestock depredations use some mix of lethal of and non-lethal responses to depredations. However, in many areas, lethal control (or attempts at it) have often been the primary response, and significant funds have been applied in the process. Surprisingly, studies on the effectiveness of lethal control have been quite mixed in their findings. Results appear to be affected by the scale at which evaluation is conducted, and evaluation can be difficult when wolf populations are growing over the evaluation period, which has often been the case.

Several studies have found that lethal control was ineffective at reducing depredations when examined at regional or state-wide levels (Wielgus and Peebles, 2014; Musiani et al., 2005; Harper et al., 2008) and sometimes were associated with increases in depredations. Harper et al. also looked at local farm clusters and found reduction in future depredations only on sheep farms and when one or more adult male ma'iinganag were removed.

Two papers have shown reductions in subsequent depredations (Bradley et al., 2015, and DeCesare et al., 2018). The effectiveness of lethal control varied with how quickly it was applied, the size of the wolf pack involved, and the number of animals removed. However, both studies were conducted in western states (Montana, Idaho and Wyoming, and Montana, respectively). Livestock rearing practices are very different in those states than in the Midwest. In addition, depredations in those states peak in the fall versus in the spring in the Midwest, and wolf pack sizes also tend to be larger. Collectively, these differences suggest it may be unwise to assume similar results will be found in the ceded territory, and the need for rigorous studies at a local level remains.

Non-lethal and preventative actions also show benefits. Most recently, USDA APHIS in Minnesota reported that in the two years their conflict prevention program has existed (2020-2021), there has

been no verified wolf damage inside turbo fladry-protected areas or where other non-lethal prevention activities have been deployed (USDA-Wildlife Services Report, 2021).

Until the relative effectiveness of lethal, non-lethal and preventative responses to livestock depredations is better understood, all these approaches will likely continue to be used in all three states in the ceded territory. It is notable that the long-term use of lethal control in Minnesota - in the absence of sport harvest - did not prevent that ma'iingan population from growing and expanding into Wisconsin and Michigan.

With these considerations in mind, the Voigt Task Force has supported the role of government agents in verifying wolf depredations and determining the appropriate responses to them. The Task Force supports the use of non-lethal responses wherever reasonable and effective, but has not opposed the limited use of targeted, lethal control in instances of verified wolf depredations as a last resort where non-lethal approaches have proven impractical or ineffective.

This same policy applies to the loss of pet animals, but not to depredations of hunting dogs that occur in in the act of hunting, or training to hunt.

Hunting Dog Depredations

Hunters assume numerous risks when training or hunting with their animals. Dogs may suffer accidents, injure themselves, be hit by vehicles, or be hurt or killed by the animals they are pursuing. These risks are inherent in these recreational activities and must be accepted by the dog owner who voluntarily subjects their dogs to them. Wolves should never be killed in response to depredations on dogs that occur in hunting or training situations.

Of the 3 states included in the ceded territory, dog depredations are highest in Wisconsin. From 2011 to 2018 (years with data available to GLIFWC from both states), dog depredations in Minnesota were 71% lower than in Wisconsin (average of 9.5 per year versus 32.5), despite the ma'iingan population being about 2.5 times higher in Minnesota. A study which compared wolf hunting dog depredations between Wisconsin and Michigan also found the relative risk of depredation to be 2.1–7.2 x greater in Wisconsin than Michigan (Bump et al., 2013).

The high levels of dog depredations in Wisconsin compared to the adjacent states appears to rest on regulatory differences between them. Minnesota does not allow hunting bears with dogs, and bear baiting in Michigan –where dogs can be used to hunt bears - begins nearly 4 months later than in Wisconsin. Bait stations appear to act as focal points which can lead to dog depredation events by putting wolves and hunting dogs in proximity.

The timing of hound dog depredations in Wisconsin is highly seasonal. And most depredations occur during the bear training period, rather than the hunting period (Bump et al. 2013). This is likely because during the training period, wolf pups are less developed and less mobile, and are still living at rendezvous sites. Their immobility makes it difficult for wolves to avoid confrontations with roaming dog packs, and the pups' vulnerability triggers aggressive protection by adults.

Wisconsin also is the only state in the ceded territory where it is legal to hunt wolves with dogs. As the February 2021 season showed, this is a highly effective but poorly regulated method. And it is possible this method may be increasing wolves' hostility towards dogs.

These factors suggest that certain regulatory changes, such as shortening the training or baiting period or banning the use of dogs to hunt bears, could substantially reduce the number of hunting dog depredations that occur in Wisconsin. However, to date hound hunting interests have eschewed restricting their activities in any way, and instead have proposed reducing the wolf population down to biologically unsound levels so they can enjoy their sport with fewer losses.

EDUCATION NEEDS

The need for accurate and effective education regarding ma'iinganag is great, yet it tends to be chronically under-addressed. There are still many people who grew up being taught wolf falsehoods and many anti-wolf organizations continue to advance these myths to advance their agenda. While it can be very difficult to alter the opinions of adults who reject science, youth or individuals with an open mind often come to understand the important ecological role of wolves and the benefits they provide. Social surveys of the general public suggest that educational efforts have been effective in changing attitudes. For example, a recent survey of Minnesota residents (Schroeder et al., 2020) found high levels of support for wolves, with 86% wanting about the same or more wolves in the state, and nearly 89% wanting about the same or more area occupied by wolves. In addition, more residents opposed hunting and trapping seasons than supported them (hunting: 48.9% oppose, 40.5% support, 10.5% neutral; trapping: 58.1% oppose, 30% support, 11.9% neutral). While state DNRs and politicians often remain more responsive to hunters, trappers, and other special interest groups, increasing public support for a sound relationship with ma'iinganag will hopefully eventually result in greater responsiveness to the public, and a greater embracing of science by policy-setters.

Education can take many different forms, and the most effective differ by audience. While the general public remains an important audience, deer hunters may be an especially important group to target. This group may be less imbedded in their opposition to wolves than bear hunters (particularly in Wisconsin) or livestock producers. In addition, while some will resist the idea, at a landscape level, deer hunters directly benefit from wolves' role in maintaining deer herd health, especially regarding diseases such as CWD. Effective education of deer hunters should eventually lead to greater support for wolves from this influential group.

Education is also needed to debunk the falsehoods which have long surrounded wolves. Both TEK and contemporary science can help dispute these falsehoods, and help people understand that many of the reasons given as to why wolves should or need to be hunted are unfounded. While a full review of these arguments and their rebuttals is beyond the scope of this document, it is worthwhile to review some of the primary ones here:

Human Safety Concerns

Many people grow up being taught to fear wolves, but fear, and actual risk of harm, are very different things. While wolves should always be treated in a respectful manner, and people should never habituate wolves to human presence, ma'iingan typically avoid people, and present very little risk. Many other animals and natural events pose far greater risk of harm, including bees, dogs, cattle, and lightning strikes. The National Highway Traffic Safety Administration estimates that nearly 200 Americans die annually from deer/vehicle accidents, while there have only been 2 documented cases of wolves killing humans in North America in modern history, one of which likely involved a wolf that had been

habituated to human presence. Given the recent study which found that wolf presence reduces the frequency of deer/vehicle collisions in Wisconsin (Raynor et al., 2021), wolf presence may overall benefit human safety.

In addition, in the very rare situations in which individual wolves act boldly or threateningly around humans, an immediate and targeted reaction by government agents is an appropriate and effective response. The argument that human safety issues justify a general hunting season is without merit.

Livestock Depredation

The negative impacts of ma'iingan on livestock is often presented as a substantial problem for the industry, and wolves have been documented killing a wide range of livestock ranging from cattle to chickens. Nevertheless, while ma'iingan depredations can be important and painful for some individual ranchers, depredation losses to wolves at an industry level have remained extremely small. For example, the US Department of Agriculture estimated that from 2019-2022, Wisconsin supported about 3.46 million cattle or calves annually, and reported that the average number of cattle or calves slaughtered in the state over 2019 and 2020 was 1.41 million (Tyler Heep, USDA, personal communication). From 2010-2018, the average number of confirmed depredations (killed or injured) of cattle in the state was 47. Thus, the number of confirmed cattle depredations in a year is similar to the number that are slaughtered every 20 minutes. While acknowledging that not every wolf depredation is confirmed and that many of Wisconsin's cattle live outside of primary wolf range, it nevertheless places the level of threat the wolf population creates for the Wisconsin cattle industry into perspective. And this impact is further reduced because unlike for losses to other predators like coyotes and bears, ranchers can be reimbursed for losses caused by wolves. In addition, losses to coyotes are likely reduced in areas occupied by wolves. Thus, while the ranching industry may face many challenges, losses to wolves is clearly not a significant one.

Regardless of the exact level of negative impacts that ma'iinganag may have on livestock producers, there are two related questions that must be considered if one is attempting to justify a hunting season on the basis of depredation losses: 1) does hunting reduce future depredations or not, and 2) do depredation losses outweigh the positive benefits ma'iinganag provide?

Evidence that hunting wolves reduces livestock depredations is extremely limited. A Montana study found that public harvest only reduced the number of statewide depredation events by 6 per year (DeCesare et.al., 2018).

Scientifically defensible data originating within the ceded territory or surrounding states is even more difficult to find, but some insights may be gained from depredation records.

If recreational hunting did reduce future depredations, one would expect fewer depredations would occur in the years which follow years with hunting seasons, versus years without them. Minnesota held hunting seasons from 2012-1014, which would presumably affect the 2013-2015 "depredation years."

While the sample size is very small (3), an average of 19 fewer verified depredations of cattle and poultry were recorded over the 2013-2015 period compared to other years over the 2011 – 2021 period (69 versus 88 confirmations per year) (USDA-Wildlife Services Report, 2021). The lower average was attributable to 2013 and 2014; 92 verified depredations occurred in 2015, slightly higher than the

average for the years not following hunts. The average recreational kill during this period was 305 wolves per year.

One might also expect the number of wolves killed in lethal depredation control to decline in years following years with hunting seasons. Depredation kill was markedly reduced in 2013, but kill was slightly higher than the average of years not following hunts in 2014 and 2015.

Of course, these correlations may be happenstance. Other factors likely also affect depredation levels. Winters which are severe for deer, for example, may make more food available for wolves, and result in fewer livestock depredations. In short, available data is inadequate to draw firm conclusions about the impact that hunting seasons had on livestock depredations in Minnesota.

Attempting to do a similar evaluation for Wisconsin is even less informative, since lethal depredation control also greatly increases during periods of delisting when wolves are also hunted, making it impossible to determine the effects of each. Nevertheless, the hunting seasons from 2012-2014 would be expected to reduce depredations from 2013-2015, and indeed, it initially appeared that this occurred. The record high levels of depredations seen from 2010-2012 (ave. 110) deps/year) fell 27% over the 2013-2015 period (ave. 80 deps/year). However, depredation levels remained low from 2016-2018, when no hunting was occurring (ave. 77 deps/year), and the wolf population was increasing, suggesting the reduction in verified depredations from 2013-2015 was likely not a result of the hunting seasons. Some have hypothesized that the low level of depredations in 2014 was due to the severity of the 2013-2014 winter, which had the highest winter severity index for deer since Wisconsin began collecting data in 1960. Similarly, some have suggested that the greater use of non-lethal responses to depredations in Wisconsin compared to Minnesota may, at least in part, explain why depredations have not increased with the wolf population in Wisconsin. The on-going lethal control of wolves in Minnesota may create voids that are filled by naïve wolves, perpetuating the problem, while Wisconsin wolves may be learning to avoid livestock through the use of non-lethal techniques, and even pass this knowledge on to subsequent generations.

The Wisconsin 2021 February season provides insight on why hunting seasons appear to have little effect on depredation levels. An analysis by Wisconsin's Green Fire (2021) found that of the 218 wolves killed in that season, only 9 (4.1%) were killed within 5 miles of a previous depredation location, 26 (11.9%) between 5 and 10 miles, and the remaining 183 (83.9%) more than 10 miles from the nearest verified depredation. Thus, given typical wolf territory sizes, the vast majority of the ma'iinganag killed were not involved in depredations. A disproportionate amount of the February kill came from public lands. While only 28% of the Wisconsin ceded territory is public, 80% of the February 2021 kill was reported as occurring on public land. Thus 4 out of 5 wolves killed came from the very areas most people consider optimal wolf habitat. This is similar to the findings of DeCesare et. Al., (2018), who found that 83% of livestock depredations, but only 41% of the sport harvest, occurred on private land in Montana.

It is also possible that wolf hunting could lead to increased depredations. Wolves are intelligent beings, and some seem to learn to live near livestock without preying upon them. However, if such a pack is stressed, such as through the loss of important pack members in a hunting season, the remaining animals may be more likely to depredate to survive.

It is difficult to fully measure every negative impact wolves may inflict on livestock, just as it's difficult to quantify every positive impact wolves provide. Undoubtedly not every wolf kill is verified, and non-lethal impacts, such as possible weight loss, are challenging to document and measure. Similarly, while the study of deer/vehicle accidents suggests Wisconsin citizens save $10.9 million a year due to wolves reducing deer presence on roadways, other major economic benefits such as improved tree regeneration, remain unquantified. However, there is scant evidence that recreational harvest seasons, at least as currently conducted, provide meaningful relief to the small number of ranchers experiencing losses, and the benefits of wolves appear to clearly outweigh their negatives. As with public safety concerns, timely and targeted responses by government agents are more likely to effectively address depredations when they occur.

Finally, research and active management to reduce the number of depredations which occur is generally seen by both wolf advocates and livestock interests as the best outcome of all. In 2020, USDA Wildlife Services in Minnesota gained funding that enabled them to substantially expand the non-lethal component of their wolf depredation program. This dedicated funding has "provided the tools and evidence to demonstrate to livestock producers and others that non-lethal preventative activities can be used to reduce wolf-livestock conflicts before damage has occurred in Minnesota" (USDA-Wildlife Services Report, 2021). Future plans for this funding include helping ranchers with proper carcass disposal, which is frequently a challenge in winter months, so that these carcasses don't attract wolves to livestock operations. Clearly, non-lethal tools can be an important component of livestock depredation management.

Population Control

Some individuals contend that the wolf population will grow "out of control" if not hunted. This is simply false. As noted above, ma'iinganag are highly territorial animals, and the combination of that behavior, and the typically limited levels of available (i.e. sick, injured, weakened) prey naturally keep wolf populations at very low levels compared to other wildlife species (or to people). Wolf populations have plateaued at modest levels in Minnesota and Michigan and were likely very close to doing so in Wisconsin prior to the February 2021 season. (The most recent population model (Stenglein et al., 2015) estimated carrying capacity in Wisconsin at 1242, including ma'iinganag living primarily within tribal reservations.)

It can also be helpful to place wolf numbers into context by comparing them to other species in the region. In Wisconsin, for example, the highest estimated wolf population in the state since recovery has occurred was about 1,126 wolves, counted at the low point in their annual cycle. Trumpeter Swans, still considered uncommon in the state, now number about 6,000. WDNR estimates the black bear population is over than 24,000, and it was believed to be over 28,000 in the mid 2010's. And the estimated deer population, *after* the 2020 hunt, was over 1.6 million, and about a half million higher than the post hunt estimate from just 6 years earlier. Of course, all these figures are dwarfed by the human population. The 2022 estimated human population for Wisconsin was 5.9 million; since 1980, the Wisconsin ma'iingan population has increased by 1,100; the human population by 1.2 million.

Wolf Impacts to the Deer Population

It is perhaps both surprising and not surprising that the myth of wolves reducing deer abundance has endured as long as it has. Many people assume that since ma'iinganag eat deer, they must reduce the deer population, but natural ecosystems cannot often be reduced to such simple calculations.

Unlike many contemporary deer hunters who view wolf sign in their hunting areas as a negative, tribal hunters and early Europeans explorers recognized the relationship between the abundance of wolves and the abundance of game animals. For example, on August 9, 1831, Henry Schoolcraft (1975) was canoeing about 18 miles south of what is currently Rice Lake, Wisconsin. He noted in his journal that "During the night wolves set up their howls near our camp, a sure sign that we were in deer country."

While wolves may affect the abundance of deer at a very local level, there is no evidence supporting the contention that wolves reduce deer at any type of landscape level.

Deer and wolves have co-evolved for at least one million years (Nelson and Mech, 1981), and deer have clearly been resilient to wolf predation. Few question the idea that both ungulate and wolf numbers were very high when Europeans first came to Turtle Island, suggesting wolves were not limiting prey abundance.

Killing a healthy deer is neither an easy nor a risk-free undertaking for ma'iinganag. Thus, wolves select young, old, injured, weakened or diseased prey. Culling these animals can have an effect like pruning an orchard; it improves the productivity and long-term health and vitality of the population.

Wolves are also only one of many factors affecting wolf abundance on the landscape. Human harvest, weather impacts, habitat quality, vehicle collisions, disease, and other predators such as bear, coyote and even bobcats, all take adult deer or fawns. In this complex environment, wolves simply are not a dominant force in determining deer numbers (Sitar and Roell, 2021).

In addition, not every deer eaten by wolves reflects a true reduction in the deer population. Wolves will readily take advantage of car-killed deer, or will take animals that have died, or are near to dying, from disease, malnutrition, hunter-inflicted wounds, or other factors.

And perhaps counter-intuitively, wolves reduce some other forms of morality for deer. The study which indicated that wolves reduce deer/vehicle accidents primarily by affecting deer behavior suggests that the number of deer killed by cars is reduced to some extent where wolves are present; the same is true of losses to coyotes, whose abundance is reduced in areas occupied by wolves. And as noted earlier, ma'iinganag likely reduce the distribution and prevalence of infectious diseases. All these factors reinforce the traditional teaching that wolves help maintain the health of the deer population across the ceded territory and elsewhere.

Thus, under normal circumstances wolves do not determine the number of deer on the landscape, so much as the number of deer determine the number of wolves. The ecologically minded deer hunter can return to the old understanding that seeing wolf sign is a reflection of a healthy deer herd in the area.

Finally, it should also be noted that while many deer hunters are never satisfied with the number of deer on the landscape, over-abundant deer populations can have highly detrimental impacts on forest health,

and, through increased disease transmission, even the health of their own populations. As has been discussed, wolves can provide positive benefits in both these realms.

Economics of Harvesting Wolves

The notion that hunting wolves can provide important income to hunters and trappers is the only common argument given for hunting wolves that does not hinge on their supposed negative qualities. Most Ojibwe feel that killing ma'iinganag only for their skin is abhorrent. However, this justification also fails from a purely financial analysis as well when applied to state wolf hunters, who collectively pay significantly to hunt wolves. For example, over the last 4 Wisconsin wolf seasons, the application and license fees collected by the state exceeded $1,525 for each animal harvested (GLIFWC unpublished data). These costs alone greatly exceed the value of the pelts (or in rare cases mounts) gained, and hunters and trappers obviously have other costs (including time, travel and equipment) associated with participating in the hunt. Only state DNRs generate income on wolf seasons.

In addition, if the individuals and organizations advancing this justification were sincere, they could be expected to support high population goals and be opposed to killing wolves during their breeding period. In most instances that has not been the case, indicating that this contention has been advanced as a false justification for killing wolves.

As each of these falsehoods is debunked, the primary motivations for killing wolves are exposed. These largely consist of killing simply to gain a trophy, or, for some (especially hound hunters who have had dogs depredated by wolves), to gain revenge for their losses. These reasons fail to meet the Ojibwe perspective that killing any animal needs to be based upon need, or the ethic of many sport hunters, who similarly contend that an animal should only be killed for a legitimate reason.

POPULATION MONITORING

The intensity of population monitoring that is required depends upon other management/stewardship decisions. Any time a state is implementing hunting seasons, annual population data should be collected. Alternatively, wolf populations not subject to annual harvests can generally be more lightly monitored, potentially saving natural resource agencies and their cooperators the substantial costs associated with annual surveys.

All 3 states in the ceded territory currently use reasonable approaches to monitoring the wolf population within them, and a duplication of these efforts to track the ceded territory population is not feasible or justified. However, if staffing permits, it would be beneficial to have tribal natural resource staff cooperating in each state's efforts to maximize our understanding of the strengths and weaknesses of each approach. For this to happen, however, the cooperation must include more than simple data collection and sharing but extend to participating in the process of generating the population estimates and interpreting the results.

It has always been difficult to know how sensitive each method is to changes in the wolf population. All methods ultimately rely on 3 basic parameters: how big is the area occupied by wolves, what is the average territory size, and what is the average pack size. Each of these parameters can be mis-measured. Average pack or territory size can be biased if most of the data is collected from non-random locations, such as only in core parts of the range, or areas with the highest prey abundance. Similarly,

some areas which might be considered occupied may not be – particularly if packs are removed or break down as a result of hunting seasons. The limitations of each method, and consideration of the wide confidence intervals they generate, should be considered anytime population model data is used to inform quota setting for state seasons.

RESEARCH NEEDS

While wolves have been heavily studied and a substantial body of TEK and western science knowledge exists, much remains to be learned, and the controversy which continues to surround the human/ma'iingan relationship spurs the need for further study. Some high-priority needs include:

Effectiveness of Lethal, Non-Lethal and Preventative Responses to Livestock Depredation

While various studies have attempted to look at the effectiveness of lethal or non-lethal responses to livestock depredations, results have often been conflicting. In addition, the studies showing the strongest positive result from lethal control have largely come from western states; the great differences in cattle husbandry from those areas compared to the Midwest raise questions about their applicability here. Development of cost-effective techniques to prevent depredations is supported by both agricultural and wolf conservation interests.

Chronic Wasting Disease (CWD)

It would be very valuable to better document ma'iingan's selectivity for CWD infected deer, and the impact of wolves' in reducing the spread of the disease. Although contrary to the Ojibwe world view, humans often weight the value of other beings primarily on the direct impacts they have on us. While wolves likely are selective for CWD infected deer and have positive impacts on prevalence of the disease, better documentation of their level of selectivity, the viability of prions that have passed through ma'iinganag' digestive system, their overall effect on disease prevalence, and the loss of this effectiveness that might result from reducing wolf populations below carrying capacity all could have important stewardship and education applications.

Evaluation Of Wolf Population Estimation Methods

Sound population figures are critical when wolves are subject to killing seasons. While the methods used to estimate populations by each state generate useful figures, they have wide confidence limits around them, and it is unclear if they function as well when applied to harvested vs unharvested populations, especially in instances where packs are lost as a result of hunting.

Health Assessments

True determination of the health of the wolf population goes beyond simply estimating the number that exist but should include understanding the health of individuals in the population, especially given the low levels which characterize wolf populations. An immediate need is to better document heartworm levels, but general monitoring of population health should be an ongoing activity. At a minimum, necropsies should be performed on an adequate sample of animals killed in any state-authorized activity, and special emphasis should be placed on examining any animal killed in the breeding season.

Harvest Models

Harvest of any species with small populations requires the utmost care. While we oppose the recreational harvest of wolves, states may unfortunately continue to have seasons. The model by Adams et al. (2008) has been frequently used to set, or at least inform, quota setting by states in the ceded territories. However, there are a several reasons why this model is likely inappropriate to use in the Midwest and may result in overharvest. Problems include: 1) most of the studies which the model is based upon were of relatively small areas, in remote locations, surrounded by areas with low wolf harvest. At this scale, immigration from surrounding areas can make high harvest levels sustainable; the authors recognized that and concluded that wolves were able to compensate for the high levels of human induced mortality in these studies "primarily via adjustments in dispersal components (i.e., local dispersal, emigration, and immigration), whereas responses in productivity or natural mortality have little or no role in offsetting harvests." However, these components lose their functionality when applied at a state-wide scale (when few wolves cross state lines), and/or at areas on the edge of wolf range where immigration from unoccupied range is not possible. 2) Most of the base studies also came from areas with very long seasons, and with limited access. Losses to poaching, vehicle accidents and lethal depredation are very low in these study areas and not comparable to the Midwest. 3) This model does not consider where the wolf population is relative to carrying capacity, suggesting the same harvest rate is sustainable at any level of the wolf population. This premise is contrary to basic population dynamics. It appears that regular application of this model may drive the population towards roughly ½ of carrying capacity, resulting in a significant loss of the ecological and cultural benefits ma'iinganag provide. More refined harvest models are needed if states continue to implement hunting seasons.

Impacts of Recreational Harvest on Ma'iingan Packs and Populations

Harvest seasons tend to focus only upon numbers: the number to be killed, and the number expected to survive. But ma'iinganag are highly social animals, and harvest seasons can have significant impacts on the social structure of a pack or the demographics of the population. These changes may in turn have repercussions on wolf behavior, such as the ability to transmit intergenerational knowledge, or alter the likelihood of committing depredations.

Harvest could also affect wolf density and reduce their ability to regulate disease prevalence or enhance tree regeneration or plant diversity.

The relatively unsophisticated season structures that have often been in place also results in very non-random distribution of harvest, particularly in Wisconsin, in seasons where a significant portion of the harvest comes through the use of hounds. Harvest can come disproportionately from public lands, and hounders can organize their killing to intentionally remove entire, specific packs.

Wisconsin wolf hunting regulations also allow the season to extend into the wolves breeding season. Killing wolves at that time undoubtedly reduces recruitment more than killing wolves months earlier.

In short, our understanding of the impacts of sport seasons on ma'iingan packs and populations is very limited, and merit better understanding if states continue holding hunting seasons.

SUMMARY

The Ojibwe world view, coupled with TEK and western science, creates a sound and defensible framework for the human/ma'iingan relationship. The ancient relationship between these two beings, as formed in the creation story and formalized in the original treaty with ma'iingan, still is appropriate and applicable today. Only by embracing this relationship can the benefits the treaty yields to humans and ma'iingan be fully realized.

In this relationship, ma'iingan is respected and appreciated. Ma'iinganag determine their own range and population levels; they live in healthy families as an integral part of an ecological community, and they provide the gifts only they can provide to all in that community, including ourselves. The ma'iingan community is not punished for the actions of a few, and are not killed for recreation or vengeance.

This, in brief, encapsulates the treaty that was made, and that will be honored.

Appendix 1. Global Indigenous Council Wolf Treaty

The Wolf: A Treaty of Cultural and Environmental Survival

THE WOLF IS KNOWN BY MANY NAMES . . .

Hó'nehe. Shó^{n}to^{n}ga. Cheétxiilisee. Šuŋgmánitu tȟáŋka. Ómahkapi'si. Mélemsʟye. Makoyi. Bia isa. Hooxei. Ruv. Tha:yö:nih. Okwaho. Othahyu·ní. Ma'iingan. Skiri. Nciʾcn. Kwewu. Wahya. Himíin. Shin-ab. Tséena. The wolf (Canis lupus) is known by many names and for time immemorial has held an esteemed place in the cultures and lifeways of the original inhabitants of this continent. The wolf has guided and influenced indigenous people in a foundational way, literally since the beginning of time. The wolf brought knowledge and understanding of Mother Earth that is mirrored in the stars. The wolf has influenced indigenous societal structures through the pack, imparting the communal responsibility to sustain life. The wolf taught many to survive by the hunt and to live in a spiritual compact of reciprocity. The wolf provided guidance for environmental stewardship and ecological balance. The wolf is a teacher, a guardian, a clan guide – a relative.

PURPOSE AND OBJECTIVE OF THE TREATY

Today the grey wolf is functionally extinct in most of its historic range. The US Fish and Wildlife Service estimates that fewer than 6,000 grey wolves presently exist in the contiguous United States. Some two-million wolves co-habited North America with our ancestors, pre-European colonization; the pre-contact wolf population estimates of scientists correlate with those of our elders. What effects the grey wolf in the lower-48 US states, impacts wolves north of the US-Canada border and south of the US-Mexico border. Like the First People of this continent, the wolf does not recognize imaginary lines transposed upon the land. To honor, recognize, and revitalize the ancient relationship we have with the wolf, it is the collective intention of we, the undersigned, to welcome the wolf to once again live beside us as Creator intended and to restore balance to Mother Earth where we are the stewards and the wolf is a protector of our lands. We will do everything within our means so that with the wolf, we will once again live in the sacred cycle of reciprocity to nurture each other culturally and spiritually. In our collective efforts to protect and recover the wolf – and by doing so protect, preserve and perpetuate indigenous cultures – this treaty is analogous to the "United Nations Declaration on the Rights of Indigenous Peoples (UNDRIP)" and the principles of the "Rights of Nature & Mother Earth."

PARTIES TO THE TREATY

We, the undersigned, including Tribal/First Nations, Traditional Societies, Spiritual Leaders, representative Tribal Organizations and Respective Leaders from each generation and from the four sacred directions of Turtle Island. We recognize Mother Earth as a life-giving force, a living entity of which human beings are a part, rather than as human property to be owned, exploited and destroyed.

ARTICLE I – CONSERVATION

Recognizing the wolf as a practitioner of conservation, we, collectively, reaffirm that our ancestors were conservationists before the term existed in the Western lexicon, and that in their honor we agree to perpetuate their principles of caring for Mother Earth that is today called conservation. Fundamental to that is respecting the interrelationships between us and "all our relations" which the wolf embodies. The wolf has a critical role in providing balance, health and structure to ecosystems which benefits a wide spectrum of life, be they two-legged, four-legged, winged, or those with roots. Grizzly bears, buffalo, beavers, songbirds, foxes, and pronghorn are among those aided by the wolf. Wolves prey on wild ungulates, those which are the most vulnerable due to age, injury or sickness, thus providing the healthy with a greater chance to survive and renew the herd. Where the wolf exists, so does balance: without overpopulations of elk, trees such as cottonwood, aspen, willow and serviceberry regenerate, providing crucial nesting and roosting sites for songbirds; enhancing root strength which protects streams from soil erosion, and in turn provides food and building elements for beavers whose dams then create ponds needed by fish; and finally, to enabling the growth of berry shrubs that provide sustenance for grizzly and black bears.

ARTICLE II – CULTURE

The wolf taught us to hunt and imparted that "those with hooves and horns" would sustain us physically, but "those with paws and claws" were to provide spiritual sustenance. Wolves gave of themselves to enable us to live the "Dog Days," offering their progeny to accompany us, to help us travel and traverse vast distances, to protect us, as their descendants – domestic dogs – do today. We commit to perpetuate and continue our spiritual ceremonies, sacred societies, sacred narratives and sacred bundles in which the wolf has a unique place, which in practice is a means to embody the thoughts and beliefs of ecological balance. Realizing that the wolf is a foundation of our traditional ways, we commit to the ideal of preservation and restoration in all aspects of our respective cultures related to the wolf, including customs, practices, naming, beliefs, songs, astronomy and ceremonies.

ARTICLE III – MANAGEMENT PRINCIPLES

The federal government has never developed a national strategy to recover wolves in the contiguous United States that is in accord with expanded protections. As a statement of sovereignty and cultural and environmental restoration we commit to rectify this omission. Recognizing that our collective objective is to see the wolf returned to areas of biologically suitable habitat on our traditional lands within the wolf's historic range pre-colonial contact, and for linkage zones to be established between the existing, fragmented populations, wolf management plans for Tribal/First Nations will be formulated from a cultural foundation, while accommodating the "best available science." We, collectively, recognize that our ancestors practiced the "best available science" in their stewardship of the land, as they lived in balance with our Mother Earth when the biomass was at its height. Spirituality informs the indigenous worldview, which includes our Traditional Ecological Knowledge (TEK). The US Fish and Wildlife Service describes TEK as "Native Science" gained "over hundreds or thousands of years through direct contact with the environment," and further expounds how TEK "encompasses the world view of indigenous people which includes ecology, spirituality, human and animal relationships, and more." Our TEK is the very definition of "the best available science." Our people applied their TEK for millennia prior to contact. "The idea that TEK has guided modern biology (or Western science) should encourage

conservation biologists to investigate TEK more thoroughly," remains the prevailing finding of the US Fish and Wildlife Service. TEK will guide our management practices for the wolf and must now become a standard applied to federal, state and provincial management plans, following the examples of Rumphius, Linnaeus, Darwin and Merriam. Patterned on traditional practices, management objectives should strive for balance between maintaining our subsistence cultures where they are dependent upon viable ungulate populations, and the true recovery of the grey wolf population in the contiguous US.

ARTICLE IV – RECOVERY OBJECTIVES

Tribal/First Nations have the legal responsibility and authority to protect our ecosystems in the best interests of our people. Our rights and interests do not stop at reservation or reserve boundaries, we have ancestral and treaty lands, Ceded Territories, and reserved rights on those lands. A multitude of scientists contributed to a United Nations report which warns that some one-million species are facing extinction. Since the Industrial Revolution, the decimation of 83% of the mammals on earth has been accelerated, resulting in the once-unimaginable reality that 96% of existing mammals on earth are either humans or livestock. By 1967, approximately 1,000 wolves survived in the US, ostensibly in the Great Lakes region; the slaughter of the wolf inspired by federal policies echoes that which resulted in the near extirpation of the buffalo and the grizzly. The wolf now occupies only 10% of its historic range and only 30% of existing suitable habitat. Tracts of current and ancestral Tribal/First Nations' territory comprise the 530,000 square miles of suitable wolf habitat in the lower-48 states. Areas of indigenous cultural significance in the southern Rocky Mountains, Grand Canyon, Cascade Mountains in Washington, Oregon and California, the Sierra Nevada and the Adirondacks all offer viable wolf habitat. The long-term survival of the grey wolf in the lower 48 depends upon the wolf's return to critical portions of its historic range. These ecosystems require healing, having lacked the presence of the wolf for multiple generations. By the US Fish and Wildlife Service's own population estimate, 6,000 wolves are below what scientists have identified as the minimum viable population size necessary to avoid extinction.

ARTICLE V – GOVERNMENT-TO-GOVERNMENT CONSULTATION

The federal government has a fiduciary obligation to Tribal/First Nations, which includes providing government-to-government consultation on any Endangered Species listing or delisting decision that impacts Tribal/First Nations. Any proposal to delist the grey wolf fits that criteria. The same issues that threatened Tribal/First Nations in the grizzly delisting struggle will resurface with grey wolf delisting: potential harm to tribal sovereignty, undermining treaty rights, stripping religious and spiritual freedoms, and detrimental economic repercussions. Government-to-government consultation must not only be "thorough" and "meaningful" as mandated by Executive Order 13175, but it must adhere to the standard of "free, prior and informed consent." In 2010, the US endorsed the United Nations Declaration on the Rights of Indigenous Peoples (UNDRIP) but has yet to honor that commitment. In defense of our rights and the preservation of the grey wolf, we, the undersigned, invoke Articles 25 and 26 of UNDRIP.

ARTICLE VI – NATIVE AMERICAN ENDANGERED SPECIES ACT (NA-ESA)

It has become the norm that federal agencies place a far greater emphasis upon the input of energy companies - with considerable influence being accorded extractive industry executives - in Endangered Species Act (ESA) listing and delisting decisions than is accorded Tribal/First Nations. That disregard of

the federal-Indian trust responsibility has prompted tribal nations to explore the formulation of a Native American Endangered Species Act (NA-ESA). Sovereign tribal lands hold several T&E species and vital habitat, and it is time for tribal people to have a greater input into the management and protection of these species that hold great cultural significance. In the present political climate, for some species an NA-ESA may be the only viable path to survival. As Tribal/First Nations, our sovereignty is consistently compromised by the US Fish and Wildlife Service and the states in respect to wildlife management, including federal administration of the ESA on tribal lands. A NA-ESA would enhance tribal sovereignty, provide vocational opportunity for tribal members, and enable the melding of contemporary biological discipline with tribal Traditional Ecological Knowledge (TEK) in management policies and practices. The NA-ESA would, in essence, be a framework document that could be adopted and amended according to the criteria of individual Tribal/First Nations, be they cultural or economic, as opposed to a "one-size fits all" imposition. We, the undersigned, will continue to evaluate the pathway to a NA-ESA.

ARTICLE VII – ECONOMICS

Recognizing the wolf as a traditional teacher and protector of our lands and people, we, respectively, will research economic development revolving around the wolf in an environmentally and culturally compatible manner, including eco-tourism models with wolf watching, photography and culturally oriented educational tourism, traditional crafts, publishing and literacy materials inspired by traditional narratives to which the wolf is central, and other beneficial by-products arising out of the wolf's gifts to us. Millions of visitors from around the world travel to Yellowstone National Park annually to catch a glimpse of the wolf, demonstrating that the wolf's hold upon the human imagination transcends ethnicity.

ARTICLE VIII – EDUCATION

Education and outreach are essential to wolf recovery. Respecting all of the teachings we have received from the wolf, we, collectively, agree to develop programs revolving around the wolf as a means of transferring intergenerational knowledge to the younger and future generations and sharing knowledge amongst our respective Tribal/First Nations to both strengthen and reignite cultural ties that in some instances have been overwhelmed by colonization. We will not adopt state, provincial or federal wolf management plans, as all are infringements of our sovereignty and do not reflect our TEK. We will prioritize vocational and educational programs for our people, so that on our lands, they will be the leaders of our culturally compatible wolf management programs. Upon the signing of this treaty, any management removal of a wolf will be undertaken with ceremony, and such parts of the wolf that have always been kept in sacred bundles or used for traditional practices will be provided to such persons qualified. We will seek to counter popular myths that have become talking points to justify the eradication of the wolf from large parts of its historic range. Contrary to popular mythology, domestic dogs pose a greater threat to people than wolves. Of an estimated 115,000 wolves worldwide, there are only ten recorded cases of fatal encounters with non-rabid wolves in the last half-century, two of those having occurred in North America. By comparison, dog bites are responsible for sixteen deaths per year in the US, with an estimated 4.7 million domestic dog bites reported annually.

ARTICLE IX – HUNTING

At the inception of our relationship with the wolf, this sacred guide instilled the values of the hunt to our ancestors. Generally, current federal, state and provincial management plans that enable and elevate trophy hunting of species of immense cultural importance are antithetical to those ancient principles. Tribal/First Nations will not allow infringements of sovereignty by the influence of any de facto sovereign. We will formulate vocational and educational programs for our people, so that on our lands, they will be the leaders of our culturally compatible wolf management programs.

ARTICLE X – RESEARCH

Recognizing that learning is a life-long process, we, collectively, agree to perpetuate knowledge-gathering and knowledge-sharing according to our customs and inherent authorities revolving around the wolf that do not violate our traditional ethical standards as a means to expand our knowledge base regarding the environment, wildlife, plant life, water, and the role of the wolf in the history, spiritual, economic, and social life of our Tribal/First Nations. We will seek input from the leading, independent biologists qualified in the study of the wolf to ensure that we continue to lead in the preservation and recovery of the wolf.

ARTICLE XI –THREATS

The US Fish and Wildlife Service estimates that approximately 6,000 wolves presently survive in nine of the lower-48 states. In three of those – Wyoming, Idaho and Montana –some 3,500 wolves have been killed since 2011 after the removal of federal protections in those states. Even without trophy hunting and trapping, studies have found that annual mortality rates in wolf packs can reach 50% but typically average around 35%. In Idaho, state managers resumed the engagement of bounty hunters to kill wolves and requested the intervention of US Department of Agriculture/Wildlife Services' airborne sharpshooters to reduce pack densities. Wyoming designated the wolf with predator status, which permitted the killing of wolves with minimal restrictions, including killing pups in dens. Wisconsin's current management plan provides for the wolf population to be culled by 60%. These examples highlight the greatest threat to the wolf – the removal of federal protections, the lack of consultation with and authoritative input on wolf recovery afforded Tribal/First Nations, and the enactment of state wolf management plans that are motivated by political interests, not scientific findings. Multiple studies have concluded that the existing wolf populations in the Rocky Mountains, Great Lakes and Southwest are below the minimum, viable population sizes to ensure their survival. These populations are also below levels considered necessary to avoid genetic inbreeding. Like threats facing the grizzly bear, the loss of genetic diversity due to small, isolated populations is a threat that must be addressed through recovery plans that prioritize connectivity.

ARTICLE XII – CONFLICT REDUCTIONS

"When I was a child, I used to ride horseback with my dad and sometimes we would see wolves, and they would never attack us. Our people lived in harmony with the wildlife, I don't believe in shooting them, they were here long before cattle or anything else," said Barbara Aripa, a respected elder of the Confederated Tribes of the Colville Reservation. A 2019 report, Wolf-Livestock Conflict and the Effects of Wolf Management (DeCesare et al), "found no evidence that removing wolves through public harvest affected the year-to-year presence or absence of livestock depredations by wolves." That conclusion

was based upon over a decade of data. Since 2014, scientific papers have diverged on whether targeted lethal removals by wildlife managers reduce livestock depredations. There is, however, consensus that proactive non-lethal conflict deterrence methods are crucial to containing wolf and livestock losses. Employing range riders and shepherds, incorporating livestock guardian dogs into conflict reduction strategies, and erecting barriers, be that fencing, fladry, penning or a combination, are effective tools in conflict reduction. Reducing attractants – particularly the removal and disposal of carcasses and separating diseased or ailing livestock – is vital to reducing potential livestock depredations. Livestock – wolf conflict has proven to be predictable and will often reoccur in the same areas. The insightful management of range units and leased lands is necessary to further minimize livestock conflicts, but it should be accepted that when livestock are released onto range units, they are vulnerable, like indigenous species, to a multitude of harms. Where the wolf presently exists, livestock depredations impact less than 1% of available livestock and less than 1% of ranchers in currently populated wolf habitat experience losses to wolves annually. Following the precedent set by some of our sister Tribal/First Nations, we recognize the need for closures to areas that offer the wolf sensitive habitat, particularly for denning sites. In the spirit of our ancestors, we will incorporate contemporary strategies in our culturally compatible conflict reduction programs; such programs will be inclusive, educational, and aim to reconnect our people with the wolf and traditional precepts of tribal society and responsibility.

ARTICLE XIII – PARTNERSHIPS

Tribal/First Nations seek to be equal partners with federal, state and provincial authorities in the true recovery and future management of the wolf. We, collectively, invite representatives of those sovereigns and Non-Governmental Organizations, corporations and others of the business and commercial community, to form partnerships with the signatories to bring about the manifestation of the intent of this treaty. Organizations and individuals may become signatories to this treaty as partners and supporters providing they perpetuate the spirit and intent of this treaty.

Ojibwe Perspectives Toward Proper Wolf Stewardship and Wisconsin's February 2021 Wolf Hunting Season

Jonathan H. Gilbert[1]†, Peter David[1†], Michael W. Price[1] and Jenny Oren[2]*

[1] Biological Services Division, Great Lakes Indian Fish and Wildlife Commission, Odanah, WI, United States, [2] Nelson Institute for Environmental Studies, University of Wisconsin–Madison, Madison, WI, United States

In February 2021, the Wisconsin DNR implemented a wolf season in which > 20% of the population was killed in 63 h. Wisconsin's Ojibwe tribes had a visceral reaction to this killing. This paper provides a perspective for this reaction by reviewing the Ojibwe relationship with Ma'iingan. This relationship maintains that Ma'iingan and Ojibwe are to be considered relatives whose fates are intertwined. Ma'iingan and Ojibwe have lived parallel histories, suffering from the effects of colonization, the decimation of wolf populations and decline of tribal culture. The Ojibwe tribes ceded vast territories in treaties with the United States while retaining common use rights, including the right to hunt and fish. These rights were reaffirmed just as wolves were reestablishing themselves in Wisconsin. The tribes continue to strengthen their culture, while wolf populations continue to recover. By examining these comparative histories, it becomes apparent that "whatever happens to one happens to the other." Unfortunately, Ma'iingan were not adjudicated during the Wisconsin treaty case, creating uncertainty over how the relationship between the Ojibwe and Ma'iingan is to be respected by the state. The tribes believe their treaty right includes protection for wolves, so that wolves can fulfill their cultural and ecological purposes. Tribes maintain that Ma'iingan should determine their own population levels, in order to provide ecological and cultural benefits. A respectful and appreciative relationship with Ma'iingan should be maintained so that the future well-being of both Ma'iingan and the Ojibwe will be assured.

INTRODUCTION

At 12:00 AM, February 22, 2021, just 50 days after wolves (*Canis lupus*) were removed from the protections of the Untied States Endangered Species Act, Wisconsin's first hunting season in over 6 years began. It ended just 63 h later. The Ojibwe tribes in the upper Midwest, including all 11 member tribes of the Great Lakes Indian Fish and Wildlife Commission (GLIFWC, **Figure 1**) had a visceral reaction to this killing. We explain the reasons for this reaction and provide some insights on the perspectives of the Ojibwe toward *Ma'iingan*, (the wolf) in hopes of increasing cross-cultural understanding and improving the human/wolf relationship.

With more permits sold (1,548 Johnson and Schneider, 2021) than wolves in the woods (1,091 Price Tack et al., 2021), the slaughter (a word intentionally selected to reflect the Ojibwe perspective) was swift – with a wolf being killed, on average, every 17 min, day and night. With hunters equipped with firearms and replaceable packs of dogs, (86% of the wolves were killed with the aid of hounds), the state's quota of 119 animals was rapidly achieved. The tribes' effort to protect their portion of the quota (81 animals) so they could provide ecological and cultural benefits critical to the tribal community, was fruitless. Before the season could be closed, 99 additional animals were killed. The reported harvest of 218 animals (Johnson and Schneider, 2021) equaled 20% of the state's wolf population; the number of unrecovered crippling loss or animals intentionally left unretrieved is unknown. Only later was it discovered that a computing error existed in the application of the harvest model (Adams et al., 2008) that the Wisconsin Department of Natural Resources (WDNR) used to inform the quota setting process (D. MacFarland per. com). GLIFWC calculates this computing error may have resulted in the quota being set about 16% higher than intended.

While the hunting season was brief, it took place during the breeding season, ensuring that its impact would not be limited to the current generation. Among the small sample of wolves necropsied after the season (n = 22) were not only animals showing the hemorrhaging and bite marks of having interacted with hounds that pursed them, but females with fetuses (GLIFWC unpublished data). On the basis of studies such as Brainerd et al. (2008) which examined the impacts of breeder loss, Wisconsin's Green Fire estimated that 24–40% of recruitment was likely lost (Wisconsin's Green Fire, 2021). While harvest models such as Fuller et al. (2003) and Adams et al. (2008) suggest the population could recover to pre-hunt levels in 2–3 years if no further harvest were to take place, the WDNR was forced to begin preparing for a fall season to comply with Wisconsin Act 169, legislation that requires an annual season whenever wolves are not on the Wisconsin or Federal endangered species list. However, the fall 2021 season was halted by a stay issued in State court (Great Lakes Wildlife Alliance et al.; v. Wisconsin Natural Resources Board et al., Circuit Court, Dane County, WI, 2021 CVoo2103).

While some in the hunting community celebrated the wolf kill (intentional phrasing), regional Ojibwe tribes mourned the unnecessary slaughter of brother wolf and the trampling of their treaty-reserved rights. Herein we elaborate on the Ojibwe perspectives toward proper human relationship with Ma'iingan.

MY BROTHER

The relationship between Ma'iingan and the Anishinaabe (Ojibwe) extends all the way back to the Anishinaabe creation story. In that story, Ma'iingan was provided by the Creator to be a companion to the Original Man. As a result of this and other teachings, Anishinaabe people consider the wolf their relative. This concept of relatedness to another species is difficult for many Western-educated thinkers to comprehend because it contradicts the principles and values of western science and Judeo-Christian society held by some people. But to the Anishinaabe, the wolf is an integral part of identity and kinship. Through stories, clan membership and culture, the wolf is woven into the spirit and identity of Anishinaabe people (other Indigenous Nations have their own, and sometimes different relationship with the wolf). When Anishinaabe people are asked to put population goals or harvest quotas on Ma'iingan, they see it as analogous to putting goals and quotas on their relatives – something unthinkable if we were talking of human relatives.

In the creation story, the Creator indicates that Ma'iingan and Original Man will always be considered as relatives and their fates would be intertwined (Benton-Benai, 2010). Thus the well-being of the wolf reflects the well-being of Anishinaabe society, a relationship that is captured in the Anishinaabe teaching: "What happens to the wolf will happen to the Anishinaabe. And, what happens to the Anishinaabe will happen to the wolf." This narrative, which has been passed down through many generations, reflects their paralleled histories.

Prior to European colonists coming into the Anishinaabe territory the Ojibwe people had a well-developed society with a governance structure, division of responsibilities passed on *via* the clan system, and a seasonally nomadic lifestyle. Ma'iingan existed across the Ojibwe territory, fulfilling their role within the upper Great Lakes ecosystems. Both Anishinaabe and Ma'iingan lived healthy lives.

When European immigrants settled along the east coast and encountered both wolves and Indigenous peoples, they responded to both similarly. Both the wolf and the Native peoples were despised and persecuted by many in the newly forming colonies.

These parallel attitudes moved west with settlers crossing the continent, as efforts to eradicate both wolves and Native Americans from the landscape continued. In the upper Midwest, four land cession treaties (**Figure 1**) were entered into in which the Ojibwe tribes ceded vast areas to the United States. The influx of European settlers coincided with the beginning of the planned extermination of wolves from that region.

While settlers put pressure on the government to eradicate wolves *via* bounties and other unlimited killing, the United States Congress was passing laws to remove Ojibwe tribes and eradicate treaty claims in direct contrast to the terms of the recently enacted treaties. Wolves proved relatively easy to kill, and eventually they were eliminated from the lower 48 states with the exception of an area of Ojibwe territory in northern Minnesota. Concurrently, the population of American Indians fell as low as 250,000 (Thornton, 1977). The 1940–1950s is known as the Termination Era when the federal government eradicated many federally recognized tribes and dissolved their reservations.

As wolves were declining so too was the free practice of the Ojibwe culture. Children were taken from Ojibwe households and sent to boarding schools where they were not allowed to practice their language or ceremony. The combination of treaty-making and treaty-breaking, termination, removal and assimilation had severe consequences for the Ojibwe culture and language.

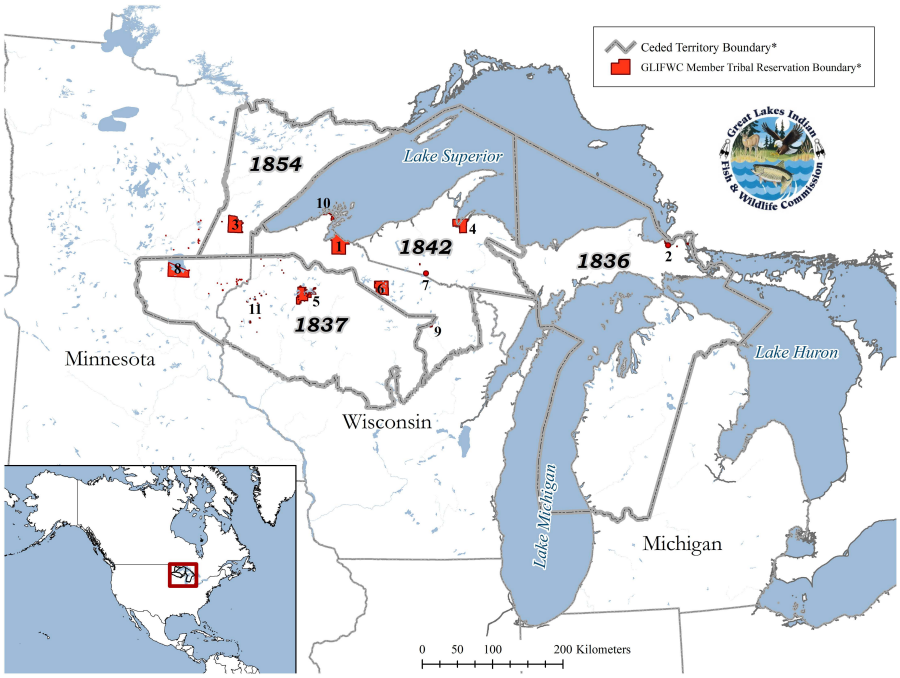

FIGURE 1 | Territories ceded to the United States in the Treaties of 1836, 1837, 1842, and 1854 in which Ojibwe tribes ceded the outlined lands and reserved the rights to hunt, fish, and gather to maintain their lifeway. GLIFWC member tribes are in red [(1) Bad River, (2) Bay Mills, (3) Fond du Lac, (4) Keweenaw Bay, (5) Lac Courte Oreilles, (6) Lac du Flambeau, (7) Lac Vieux Desert, (8) Mille Lacs, (9) Mole Lake, (10) Red Cliff, and (11) St. Croix]. *The ceded territory and reservation boundaries are representations and may not be the legally binding boundary. Map created using Ceded Territories Boundary Version 2.1.

In the 1960s, the fates of both Ma'iingan and the Ojibwe improved. The publication of Rachel Carson's *Silent Spring*, and the passage of the Civil Rights Act, allowed a new consciousness to emerge relative to ecology and equality. Additionally, the Indian Civil Rights Act was passed (1968), the Indian Education Act (1972); the American Indian Self-determination and Educational Assistance Act (1975), and the American Indian Religious Freedom Act (1978). This period also marked the passing of the Endangered Species Act (1973), and the following year, wolves finally had federal protection.

THE REAFFIRMATION OF TREATY RIGHTS

While most people think that the treaties between the tribes and the United States government granted rights to the tribes, the truth is that the treaties granted rights to the United States, and any rights that the tribes held and did not specifically cede were retained, including the rights to make their living by hunting, fishing and gathering. The Ojibwe tribes in the upper Midwest ceded large areas of what is now known as Michigan, Minnesota, and Wisconsin to the United States (**Figure 1**). In these treaties the signatory tribes reserved the right to remain in the ceded territories and to continue to live as they always had by fishing, hunting, and gathering. They relied on these activities to meet their needs for foods, medicines, materials for clothing and housing, and other utilitarian, spiritual and ceremonial purposes. Nevertheless, over time tribal members exercising these treaty-reserved rights were often arrested and charged under state laws.

In the mid-1980s the Ojibwe tribes in Wisconsin sued the state contending that their treaty rights continued to be valid and that tribes should have the sovereign prerogative to set their own natural resource regulations. As this treaty case unfolded, wolves from the Minnesota population began to reestablish themselves in Wisconsin. As in colonial times, many in the non-Indian community viewed both of these events as threats (David, 2009).

The tribes ultimately prevailed in this and related suits [see *Lac Courte Oreilles Band of Lake Superior Chippewa Indians v. Wisconsin, 775 F. Supp. 321 (W.D. Wis. 1991)* and *Minnesota v. Mille Lacs Band of Chippewa Indians, 526 U.S. 172, 176–177 (1999)*]. In these cases, it was found that the signatory tribes retained the right to harvest up to 50% of the harvestable surplus of fish and wildlife under their own set of rules and regulations, enjoining the states from enforcing state rules. Thus began the implementation of the tribes long-withheld exercise of treaty rights.

Subsequent to reaffirmation of the treaty rights, the tribes continued to reassert their sovereignty in a variety of venues including language revitalization and the reemergence of spiritual practices. Simultaneous with this cultural recovery, Wisconsin's tenuous Ma'iingan population grew in numbers and range.

Except during recent periods marked by recreational wolf killing, both the assertion of tribal sovereignty and the health of the Ma'iingan population have been greater than at any time in recent history.

By examining these comparative histories, it becomes apparent (or is an arguable logical perspective) that "What happens to the wolf will happen to the Anishinaabe, and what happens to the Anishinaabe will happen to the wolf." After the controversial February 2021 Wisconsin wolf hunt, many Anishinaabe people were traumatized and outraged. The wolf hunt was perceived by many as an assault on family members, and many felt – and continue to feel - compelled to protect their family. The Ojibwe mourned not only the loss of wolves, but the loss of Mokaan-giizis, Migizi dodem (Joe Rose Sr., Eagle Clan), a deeply respected elder of the Mashkiziibii (Bad River) Tribe and lifelong wolf advocate, who walked on in the midst of this short, brutal season. Many Ojibwe and non-Ojibwe people contended he went to help killed Ma'iingan journey to the afterlife.

TREATY RIGHTS AND MA'IINGAN

Existing treaty cases do not define the full extent of treaty-reserved rights. Notably, at the time of the final judgment in the Wisconsin case, Ma'iingan was classified as a federally endangered species and the state had little legal authority over wolves. In an update to the Wisconsin judgment [*Second Amendment of the Stipulations Incorporated in the Final Judgment, Lac Courte Oreilles Band of Lake Superior Chippewa Indians v. Wisconsin, Case No. 74-C-313-C, at 41–43 (March 15, 2011)*] the tribes and the state agreed that tribes should be required members of any wolf committee the state establishes. The state and the tribes agreed that consultation should take place and all attempts at consensus should be made in any wolf management action taken by the state.

The fact that Ma'iingan were not adjudicated during the Wisconsin trial or in any subsequent action creates uncertainty over how the unique relationship that exists between the Anishinaabe and Ma'iingan is to be recognized and respected by the state. Unlike other species litigated in the Wisconsin suit, Ojibwe people generally object to the recreational harvest of wolves. The tribes believe that their treaty right includes the right to protect wolves, so that living wolves can fulfill their cultural and ecological purposes.

In the instance of the 2021 February season the WDNR did not conduct the government-to-government consultation and attempts at reaching consensus with treaty tribes that is required by the federal treaty lawsuit case. Nevertheless, the WDNR pledged to honor the tribal declaration (of half of the quota attributed to ceded lands) while understanding that the tribes' intent was to protect those Ma'iingan from harvest. However, a lack of adequate harvest control mechanisms resulted in the 83% quota exceedance (218 harvested of a 119 quota) discussed above, rendering the state's pledge moot.

The Ojibwe contend that this gross overharvest is not only culturally abhorrent but threatens resources the tribes depend upon.

ECOLOGICAL AND CULTURAL SERVICES PROVIDED BY MA'IINGAN

The Anishinaabek relationship with Ma'iingan led them not to exterminate wolves, but to learn from, understand and accept them. In recent years western science added to this understanding, as it documents the ecological and social services wolves provide. What follows is not intended to be a thorough and comprehensive review of these ecosystem services, but some examples to illustrate the role of wolves in healthy ecosystems.

Historically, wolf reintroduction has resulted in increased biodiversity and ecological productivity in regions such as Yellowstone, where wolves were reintroduced in the late 20th century (Ripple and Beschta, 2012; Martin et al., 2020). The presence of wolves on a landscape can trigger a top-down trophic cascade, where a carnivore limits herbivore populations by direct predation, thereby allowing understory native plant species to regenerate (Ripple and Beschta, 2012; Ripple et al., 2014). These trophic effects have been seen to increase carbon storage capacity in boreal ecosystems, mitigating the effects of climate change (Ripple et al., 2014; Schmitz et al., 2014).

While not yet as extensively studied as the Yellowstone area, Ma'iingan affect landscapes in the Midwest as well. Wolf presence simultaneously supports the regeneration of herbaceous and woody plant species preferred by deer such as maple, hemlock, pine, spruce, and understory forbs (Flagel et al., 2016; Russell et al., 2017; Waller and Reo, 2018). In north-central Wisconsin, wolf presence was directly correlated with higher percentage cover and species richness of forb species in white cedar wetlands (Callan et al., 2013). These effects often have direct significance to Anishinaabe; plant species that benefit from these trophic cascades often have important medicinal, ceremonial, and utilitarian uses.

Ma'iingan prey upon the wild ungulate species that they co-evolved with, historically contributing to the health of white-tailed deer populations in the Great Lakes region since pre-European settlement (David, 2009). Ma'iingan likely help regulate the spread of contagious diseases such as Chronic Wasting Disease (CWD), a highly contagious, neurodegenerative prion-caused disease infecting four North American cervid species, including white-tailed deer (Wild et al., 2011; Oliveira-Santos et al., 2021). CWD is prevalent across the Midwest states, particularly in Wisconsin where 32 counties have reported CWD cases in free-ranging cervids (Centers for Disease Control and Prevention [CDC], 2021). The most effective control methods are still unclear, but studies have shown that top predators like the gray wolf can selectively predate on infected deer before human hunters are able to identify symptomatic individuals – which in turn likely reduces the spread and persistence of CWD in a system and potentially stops CWD emergence in new systems (Wild et al., 2011; Uehlinger et al., 2016).

Additionally, a recent study showed a significant reduction in CWD prions in the excrement of mountain lions fed CWD-infected meat, suggesting that the digestion system of top predators can be an effective mechanism for reducing environmental CWD contamination (Baune et al., 2021).

Deer are an important protein source for the Ojibwe tribes, and Ma'iingan are seen as a crucial element of defense against the spread of CWD in the ceded territory. Currently, exercise of the treaty right is limited to public lands in the ceded territory. Eighty percent of the February wolf kill in the ceded territory came from public lands, which make up only 28% of the area (GLIFWC, unpublished data). Thus, the very lands the tribes depend upon for providing venison and other harvested resources are the same lands which disproportionately lose the ecological benefits Ma'iingan provides.

Finally, humans benefit from wolves in non-ecological ways as well. For example, a recent study found a significant reduction in deer-vehicle collisions in Wisconsin, primarily as a result of wolves' influence on deer behavior, saving up to $8 million per year statewide (Raynor et al., 2021).

DISCUSSION

One of the seven primary teachings of the Ojibwe, humility (along with love, respect, courage, honesty, wisdom, truth), applies here as a reminder that our understanding of wolves is far from complete. Just as we understand wolf ecology much more now than we did 20 years ago, we will understand much more 20 years from now. Embracing humility from an ecological perspective suggests we are wise to assume that Ma'iingan – a being which occupied this region for thousands of years before being extirpated – has functions and benefits of which we are still ignorant. In the lack of perfect understanding, we maintain it is both arrogant and ecologically foolish to reduce or eliminate wolves from large parts of the landscape that wolves themselves find appropriate.

Looking forward, it is unclear if or how state and tribal wolf objectives can be meshed, particularly as long as the WDNR remains under the direction of, or are most responsive to, traditional resource harvesting interests.

While many in the non-Indian community disparage the application of Ojibwe cultural perspectives in wolf stewardship (a term more aligned with the Ojibwe world view than "management"), they often overlook the cultural underpinnings of wolf management in the non-tribal community. While traditional Ojibwe teachings may seem outdated to some, they can directly inform appropriate Ma'iingan stewardship today. And they suggest a pathway based on embracing ecological principals, sound science, and human responsibility for co-existence.

In this view, Ma'iingan are allowed to determine their own range and population levels, so that they can provide ecological benefits in all areas of suitable habitat. In addition, wolves are not killed without sound and significant justification – as should be the case for any species. And a respectful and appreciative relationship is maintained.

While simple and straightforward, this approach is radically different from most wolf management traditionally embraced by state and federal natural resource agencies. However, we contend that the agencies that do so will find a large tribal and non-tribal public already eager to embrace an ecologically defensible and scientifically sound approach. In this way tribal perspectives can be incorporated into state's approach to Ma'iingan stewardship.

United States Department of the Interior

OFFICE OF THE SECRETARY
Washington, DC 20240

D. Preston Cole, Secretary
Wisconsin Department of Natural Resources
101 S. Webster Street PO Box 7921
Madison, WI 53707-7921

Dear Secretary Cole:

In November 2020, the U.S. Fish and Wildlife Service (Service) published a final rule to remove gray wolves from the list of threatened and endangered species (Removing the Gray Wolf From the List of Endangered and Threatened Wildlife, 85 Fed. Reg. 69778, Final Rule November 3, 2020). Gray wolves are recovered in the Great Lakes region and this success is a testament to the hard work and collaboration between the State of Wisconsin, Native American Tribes, federal agencies, and local partners.

As you consider next steps for wolf management in Wisconsin, we ask that you consult and coordinate closely with Native American Tribes in the Great Lakes Region. The Red Cliff Band of Lake Superior Chippewa Indians of Wisconsin, Bad River Band of the Lake Superior Tribe of Chippewa Indians of Wisconsin, Lac du Flambeau Band of Lake Superior Chippewa Indians of the Lac du Flambeau Reservation, St. Croix Chippewa Indians of Wisconsin, and Sokaogan Chippewa Community (collectively, Ojibwe Tribes) have off-reservation reserved treaty rights that stem from their 1837 and 1842 Treaties with the United States. The Ojibwe Tribes' reserved treaty rights have been upheld in a series of federal court cases, which recognize the Tribes' rights not only to take key species, but also to conserve and protect them to ensure healthy populations and protect vital ecosystems that support the exercise of treaty-reserved rights to hunt, fish, and gather other species.

The Tribes are therefore free to use their equal share of any quota set for state-sponsored wolf hunts for protective purposes rather than to take wolves. It is the Department's view that the State of Wisconsin must honor the Ojibwe Tribes' reserved rights, including their right to protect rather than take wolves, as it undertakes the next round of planning for gray wolf hunts under Wisconsin state law.

We appreciate your efforts and continued collaboration in managing wolves moving forward. Please do not hesitate to contact us or Principal Deputy Director Martha Williams, U.S. Fish and Wildlife Service at (202) 208-4545, with any questions.

Sincerely,

JAN 25 2022

Bryan Newland
Assistant Secretary, Indian Affairs

Wolf Management Plan Public Comment

To whom it may concern,

This is Brandon Bleuer, Forestry and Wildlife Division Manager for the Ho-Chunk Nation Department of Natural Resources. I am writing today on behalf of the Ho-Chunk DNR. I also served as a member of the Wolf Plan Writing Committee. First off, the Wisconsin DNR needs to continue government-to-government consultations with the 11 federally recognized tribal nations. One recommendation would be to develop a plan for regular check-ins throughout the year with tribal Natural Resources and Cultural Resources departments to get feedback on the current state of wolf populations from a tribal perspective. This can be done through phone calls or in-person meetings. These meetings would be a good time for the Wisconsin DNR to work collaboratively with tribal nations on data collection initiatives regarding wolf populations and landscape use.

The focus on data collection and science-based decision-making is a welcome addition to the proposed plan. Citizen and stakeholder input is important, but special interest groups and political officials do not dictate wildlife policy. The decisions behind wildlife policy need to come from state and tribal wildlife professionals. The removal of a numerical population goal is another supported addition to the plan. As more information is gathered about how wolves utilize the landscape and the estimated carrying capacity of the habitats they utilize, decisions such as harvest quotas can be made.

The revision of wolf management zones is a tool that can be utilized to help manage wolf populations. Again, tribal consultations need to be had before these boundaries are set and harvest quotas are set. This is particularly important for the Ho-Chunk Nation because there is not a "no harvest" buffer zone around Nation lands. A majority of Nation lands in Jackson and Clark Counties are bordered by or in close proximity to state and county forest lands that are open to public hunting. Hunting on these lands could directly affect wolf pacts that regularly utilize Nation lands. It should be recommended that wolf harvest be primarily directed at areas that are primarily privately owned and have many wolf conflict issues.

There needs to be further research on non-lethal means of conflict abatement. The Ho-Chunk DNR would like to recommend that this be made a priority in the plans for data collection. Continuing to offer non-lethal abatement strategies to private landowners who have conflict issues needs to remain a priority. For this and all data collection efforts, the Ho-Chunk DNR would like to partner with Wisconsin DNR to conduct research.

Sincerely,
Brandon Bleuer
Forestry and Wildlife Division Manager

February 28, 2023

The Lac du Flambeau Band of Lake Superior Chippewa Indians (the Tribe) provides these comments to the Ma'iingan (wolf) management plan being drafted by the Wisconsin Department of Natural Resources (WDNR).

The Lac du Flambeau Tribe opposed the delisting of ma'iingan in 2012 and continues to fight for the protection of ma'iingan through resolution number 382(12) which reads:

Whereas, the Lac du Flambeau Tribe strongly believes that the wolves are an asset and should be protected; wolves are an important part of the ecosystem and are just starting to recover in Wisconsin after being on the brink of extinction; therefore be it;

Resolved, by this Council, in Regular Session assembled, hereby goes ON RECORD to OPPOSING the wolf hunting and trapping season.

The Lac du Flambeau Band of Lake Superior Chippewa Indians again opposed the hunting of ma'iingan in 2016 with resolution number 203(16) which declares the Lac du Flambeau Reservation a sanctuary for ma'iingan and other threatened, endangered and rare animals. Killing of these animals is a criminal act within the exterior boundaries of the reservation.

We reiterate that our Tribe ***has not*** been consulted with directly by the WDNR regarding our individual concerns with the hunting of wolves and the protections needed for our relative, the ma'iingan. The Tribe would only agree to consultation if there was an agreeance to actual implementation of Tribal comments and concerns.

WDNR did not take Tribal comments into consideration prior to the 2021 Wolf hunt, leading to a harvest that exceeded the limits within the first three days.

Through the WDNR's admittance in its own draft plan Wisconsin residents in a recent survey feel ma'iingan are special animals that deserve our admiration, that we should be able to co-exist, are important and that previous generations were wrong in eliminating ma'iingan from the landscape.

Lac du Flambeau Tribe does not see how WDNR plans on incorporating all Tribal ma'iingan management plans into this draft Wolf Management Plan. If the Tribes and WDNR are supposed to be co-managers of natural resources within the ceded territory as affirmed by Assistant Secretary Newland, then there should be more of Tribe's management plans incorporated in the draft plan then just website links.

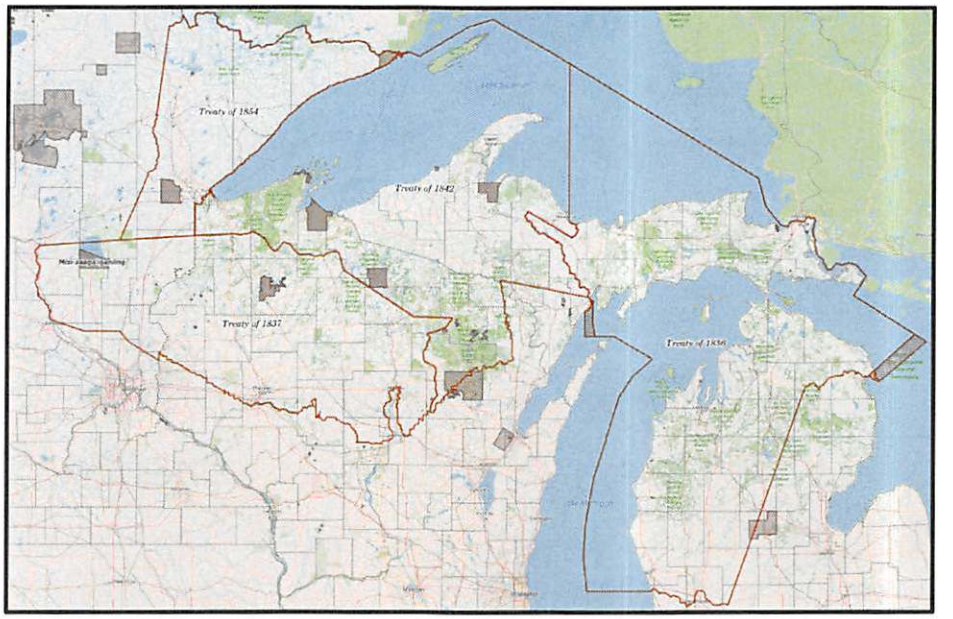

Figure 1. Map of Ceded Territory and Tribal lands.

The WDNR plan does not list all the Tribes in Wisconsin, which could lead to unintentional violations of any Tribal ordinances by Wisconsin residents.

We have specific concerns on how the population estimates were developed and how removal of a significant keystone species will not pose a detrimental impact to the balance of our ecosystem and to our cultural ties to our relative.

The proposed plan does not go into depth on climate impacts to ma'iingan, only references that WDNR will be "explored" by a later date. The Tribe already has a complete set of climate adaptation actions that are part of our Tribal Climate Resilience Plan that can be utilized in this management plan.

Lastly, the management plan does not go into depth in certain areas or has missing information, which could have been resolved by having a meaningful Tribal consultation with the Lac du Flambeau Tribe.

Thank you for the opportunity to provide these comments on the draft Wisconsin wolf management plan. If you have any questions, or would like additional information, please contact me at [redacted] or at [redacted]

RE: Red Cliff Band of Lake Superior Chippewa's Treaty Natural Resources Division's Comments on the Wisconsin Department of Natural Resources' Draft Wisconsin Wolf Management Plan

The Red Cliff Band of Lake Superior Chippewa's Treaty Natural Resources Division (hereafter "TNR") respectfully submits the following comments on the Wisconsin Department of Natural Resources' (hereafter "WDNR") Draft Wisconsin Wolf Management Plan (hereafter "draft Plan"). The Red Cliff Band, known as Gaa-Miskwaabikaang, is a federally recognized tribal nation that retained the inherent right to hunt, fish, and gather "with the other usual privileges of occupancy" within ceded territories (hereafter "Treaty Rights") under several treaties. These rights were affirmed in court under the 1837 Treaty of St. Peters, the 1842 Treaty of LaPointe, and the 1854 Treaty of LaPointe.[1,2,3] Our authority as a sovereign nation includes exercising stewardship responsibilities of our **inawemaaganag** (relatives), who are often called "natural resources", across ceded territory upon which meaningful exercise of our Treaty Rights is based. This stewardship includes an obligation to protect and preserve all our relatives, whatever their ecosystem role or relationship with us may be. These authorities provide us opportunities and the responsibility to submit comments to support, protect, and preserve treaty relatives for the next seven generations within ceded territories and the sacred waters of **Anishinaabeg Gitchigami** (Lake Superior). This includes our responsibility to help protect and steward Ma'iinganag, our sacred wolf relatives.

Sacred Relatives and Treaty Rights

Ma'iinganag aren't a "resource" to be harvested, but a relative to care for. The WDNR has heard from Tribes that Ma'iingan are, and have long been, a sacred relative of the Anishinaabe. Ma'iingan has a significant role in one of our creation stories. We are taught that Ma'iingan and Wenaboozhoo were told by Creator that they would forever be brothers and that their fates would be forever tied to one another. They were told that they would both be feared and misunderstood.[4] Our Tribal Historic Preservation Officer has told us that any harm done to Ma'iingan is harm done to our brother, anyone hunting Ma'iingan is hunting our brother, and anyone who kills Ma'iingan kills our

[1] 1837 Treaty of St. Peters, July 29, 1837
[2] 1842 Treaty of LaPointe, October 4, 1842
[3] 1854 Treaty of LaPointe, September 30, 1854
[4] Great Lakes Indian Fish & Wildlife Commission. "Comments on the Proposed Rule to Remove Ma'iingan from the List of Endangered and Threatened Wildlife". 21 June 2019.

brother. We also know Ma'iinganag to be an apex predator and a key indicator of overall health of an ecosystem. Ma'iinganag act as a steward of the land just as we do. This stewardship helps to maintain balance and ensures that some animals are harvested to allow for other plants and animals to thrive.

Specific Concerns with the draft Plan

We appreciate the WDNR recognizing the need to include Tribal staff in the review and development process of the draft Plan. While the draft Plan inherently contrasts the wishes of Gaa-Miskwaabikaang as a people who see Ma'iinganag as brothers, we do recognize that current state law could not allow drafting of a plan that did not consider state licensed harvest and that the drafting process included compromises made to help protect Tribal wolf packs such as the development of tribal subzones. We appreciate the department's recognition of the fact that each Tribe, their lands, the movements of ma'iingan and other wildlife on and near those lands, and each Tribe's knowledge of, and relationship with, local ma'iingan packs is unique. That recognition is apparent in the recommendation and incorporation of unique boundaries in the proposed tribal subzone and a welcome addition to the draft plan. We request that the tribal subzone harvest limit be set at no higher than 1 wolf annually, and further, that any wolves removed from the tribal subzone during the course of the year under auspices of lethal depredation control activities or confirmed illegal kills, be applied toward the subzone harvest limit for a given year.

Other specific comments on the draft plan are as follows:

- Section 4: *Wolf Management in Wisconsin: From Recovery to Sustainable Management*: Gaa-Miskwaabikaang supports the WDNR's decision to move away from a numeric population goal. We believe that allowing current ecosystem and landscape conditions to guide stewardship actions will lead to a healthier environment. Management to a numeric goal can be fraught with problems, particularly given potentially large annual swings in population estimates due to survey conditions, various levels of public acceptance of those estimates, and lack of agreement on what number of animals would be "appropriate" on the landscape, or at a local level, at any given point in time. Such an approach often leads to dynamic and unnecessary fluctuations in quota and tag allocations from year to year that result from chasing an imprecise and moving numeric target.
- Product B2c: The WDNR should not be required to compensate hunters for the loss of hunting dogs if the incident occurs in or around an area identified as a Caution Area. The WDNR has provided adequate resources for hunters to avoid these areas. These resources include the WDNR's webpage on *Dog Depredations by Wolves in Wisconsin* and the *Gray Wolf Depredation Mapping Application*. Additionally, if a dog was trained for wolf hunting or ever used for wolf hunting then WDNR should not be required to compensate hunters for the loss of the dog if depredated during bear season. We recommend that the WDNR pursue administrative rules to establish these restrictions on existing statute associated with compensating hunter for the loss of hunting dogs.
- B6h: Any training provided to WDNR staff regarding *wolf conflict management* should also be offered to Tribal and inter-tribal staff.
- Product C2h: Gaa-Miskwaabikaang and other Tribes have shared their firm opposition to the use of hunting dogs during any potential wolf seasons. We adamantly oppose any such action to pursue administrative rules to facilitate the use of hunting dogs in ways that will or may lead to hunting dog-Ma'iingan interactions. This includes a season that would allow for the training of hunting dogs for Ma'iingan season.
- Product D1e: We do not support a private landowner receiving any part of Ma'iingan. This allowance of "careful discretion" leaves leeway for inappropriate behavior and could incentivize the illegal harvest or abuse of depredation control permits. Additionally, the WDNR is aware (as noted above) of Ma'iingan's cultural significance to us. As such, the WDNR's should prioritize offering Ma'iinganag's body to Tribes or tribal entities first. Only after that should the WDNR consider contacting educational entities referenced in *Product D1e*.
- We recommend the WDNR take additional action to ensure that Ma'iinganag are not accidentally killed. One easily implementable action would be a return to a prohibition against all coyote harvests during firearms deer seasons. A Ma'iingan who was collared by our staff was killed by a hunter who mistook her for a coyote this past deer rifle season.

We remain committed to protecting all of our inawemaaganag (relatives) including the Ma'iinganag (wolves), nibi (water), aki (land), and air of our current and ancestral homelands for our people and the generations to come. Preserving the environment means preserving our treaty rights, our traditional life ways, and our sacred landscapes. Miigwech (thank you) for the opportunity to submit comments. We welcome follow-up questions or further discussion if desired.

Sincerely,

Andrew Edwards

WISCONSIN LEGISLATURE
P.O. BOX 8952 • MADISON, WI 53708

February 13, 2023

Secretary-designee Adam Payne
Wisconsin Department of Natural Resources
101 S. Webster Street
P.O. Box 7921
Madison, WI 53707-7921
Delivered Electronically
Open Letter

Dear Secretary-designee Payne,

We want to thank you and the Department of Natural Resources (DNR) for the opportunity to provide feedback on the proposed Wolf Management Plan.

Right out of the gate, we have a major concern with the fact that the proposed plan has no prescribed population goal.

When wolves were removed from the endangered species list in January of 2021, the DNR showed just how unprepared – or unwilling – they were to have a healthy and successful hunting season. They sat on their hands and slow-rolled a hunt under the guise of not having an updated plan, ultimately being forced by a judge to adhere to state law and hold the season in February.

In the summer of 2021, the Natural Resources Board approved a 2021-22 fall harvest quota of 300 wolves, only to encounter yet another lawsuit from special interest groups on the left. These groups prevailed, with a Dane County judge requiring the promulgation of a permanent rule and an updated wolf management plan.

Now, we have a proposed wolf management plan that has no prescribed population goal, opening the door for lawsuit after lawsuit regarding future harvest quotas set by the Natural Resources Board. We see right through this – the whole state can see right through this.

This isn't a partisan issue. Both U.S. Senators from the great state of Wisconsin are in favor of the state controlling our wolf population, your employees on the ground are in favor of the state

controlling our wolf population, and people all across Wisconsin are in favor of the state controlling our wolf population.

The blatant disregard to a prescribed population goal falls in line with that of a judge from Dane County – completely out of touch with how the overpopulation of wolves has negatively impacted families, farmers, deer hunting, tourism, property values, and communities throughout our state.

We stand with the 36 counties from all across Wisconsin who have passed resolutions in favor of setting a wolf population goal of 350 or less, and request that the department take this under serious consideration prior to moving forward with this rule.

Finally, we would be remiss if we didn't include a request to the DNR asking that the Department work with the US Fish and Wildlife Services to delist the grey wolf. The size of the wolf population does not warrant their placement on the endangered species list, and no solid data has been provided to back this decision made by a judge in California. The task of managing Wisconsin's wolves should be returned to Wisconsin, where the DNR can enforce a strong and science-based management plan for the safety of our citizens and the wellbeing of our rich natural resources.

Sincerely,

Mary Felzkowski

RESOLUTION 33 2015
RESOLUTION TO SUPPORT DNR's GOAL OF 350 OR LESS WOLF POPULATION IN WISCONSIN

INTRODUCED BY: Land and Water Conservation Committee

INTENT & SYNOPSIS: To support the WI DNR's goal of 350 or less Wolf Population in WI.

FISCAL NOTE: None

WHEREAS: the WI DNR established a wolf population goal of 350 animals in 1999, and reaffirmed this population goal in 2007, based on prey availability and human population density, and nothing has happened to increase prey availability or decrease human density in the intervening years, and

WHEREAS: the WI DNR plans to review and revise the previous wolf management plan, adopted in 1999 and revised in 2007.

WHEREAS: the Wisconsin Wildlife Federation and WI Farm Bureau have officially approved a WI wolf goal of 350 or less.

WHEREAS: the Wisconsin Conservation Congress Spring Hearings (2011) overwhelmingly supported a WI wolf population goal of 350 or less.

WHEREAS: twenty county boards in northern and west central Wisconsin have passed resolutions that recommend a wolf population goal of 350 or 350 or less.

WHEREAS: Wisconsin's residents have experienced depredations and threatening incidents involving wolves, including 81 incidents to animals and 6 threats to human safety in 2013, occurring in 21 counties, and

WHEREAS: the high predator population, in particular wolves, has resulted in the reduction of the deer population where wolves are plentiful, reduced hunting opportunities, curtailed livestock and pleasure horse activities, and are a danger to pets and people,

NOW THEREFORE, BE IT RESOLVED by the Adams County Board of Supervisors hereby advises that Wisconsin approve a wolf population goal of 350 or less in the next revision of the Wisconsin Wolf Plan, and

BE IT FURTHER RESOLVED: That the Adams County Board of Supervisors requests that the Wisconsin DNR and other partners implement meaningful population controls in the next Wisconsin Wolf Plan to bring the wolf population to goal levels, and

BE IT FURTHER RESOLVED: That the Adams County Board of Supervisors requests that the Wisconsin DNR not relocate wolves that have caused problems in Wisconsin or other areas into any county in Wisconsin.

Recommended for adoption by the Land & Water Conservation Committee this 11th day of May, 2015.

STATEMENT OF EXPLANATION

Resolution No. 08 - 22

RESOLUTION TO SUPPORT A GOAL OF LIMITING THE WISCONSIN WOLF POPULATION TO 350 ANIMALS IN THE STATE OF WISCONSIN DEPARTMENT OF NATURAL RESOURCES WOLF MANAGEMENT PLAN - RANDY SCHOLZ

Passage of this resolution will encourage the Wisconsin Department of Natural Resources to have a goal to limit the wolf population to 350 animals in the State of Wisconsin as part of the DNR's Wolf Management Plan.

Resolution No. 08 - 22

RESOLUTION TO SUPPORT A GOAL OF LIMITING THE WISCONSIN WOLF POPULATION TO 350 ANIMALS IN THE STATE OF WISCONSIN DEPARTMENT OF NATURAL RESOURCES WOLF MANAGEMENT PLAN - RANDY SCHOLZ

WHEREAS, the Wisconsin Department of Natural Resources (WDNR) established a wolf population goal of 350 animals in 1999, and reaffirmed this population goal in 2007, based on prey availability and human population density; and

WHEREAS, the WDNR plans to review and revise the previous wolf management plan, adopted in 1999 and reviewed and revised in 2007; and

WHEREAS, the Wisconsin Wildlife Federation, Wisconsin Farm Bureau, and the Wisconsin Conservation Congress (2011, 2013, 2021), officially support a Wisconsin Wolf population goal of 350 or less; and

WHEREAS, thirty-six (36) county boards have passed resolutions that recommend a Wisconsin wolf population goal of 350 animals or less; and

WHEREAS, Wisconsin's residents have experienced depredations and threatening incidents involving wolves, including 107 officially listed conflicts in 2021; and

WHEREAS, the high predator population, in particular wolves, has resulted in the reduction of the deer population where wolves are plentiful, reduced hunting opportunities, curtailed livestock and pleasure horse activities, and are a danger to pets and people.

NOW, THEREFORE BE IT RESOLVED, that the Chippewa County Board of Supervisors does hereby support a wolf population goal of 350 or less animals as part of the next Wisconsin Wolf Management Plan; and

BE IT FURTHER RESOLVED, that the Chippewa County Board of Supervisors encourages the WDNR to include elected officials from counties with high wolf conflicts in the DNR Wolf Advisory Committee; and

BE IT FURTHER RESOLVED, that the Chippewa County Board of Supervisors requests that the WDNR and other partners implement meaningful population controls in the Wisconsin Wolf Management Plan; and

BE IT FURTHER RESOLVED, that the Chippewa County Board of Supervisors requests that the WDNR not relocate problem wolves from other counties in the state into Chippewa County; and

BE IT FURTHER RESOLVED, that the Clerk shall forward a copy of this resolution to the offices of the Wisconsin Governor, Secretary of the WDNR, Preston Cole, Secretary of DATCP, Randy Romanski, and the state legislators who represent Chippewa County.

Forwarded to the County Board by the Land Conservation and Forest Management Committee.

FINANCIAL IMPACT:

There is no fiscal impact to Chippewa County by passage of this resolution.

Clark County, WI Founded In 1853					
	Type/Number	**Resolution 5-2-22**			
	Title	**Supporting Changes to Wolf Population Management**			
	Overview/Synopsis	To support a statewide gray wolf population goal of 350 or less and to oppose the Wisconsin DNR from relocating problem wolves into Clark County			
	Submitted By	Executive Committee			
	Fiscal Impact	No fiscal impact			
	Review (Initial & Date)	Legal	2/16/22	Finance	2/18/2022

WHEREAS, the Wisconsin DNR established a statewide gray wolf population goal of 350 in 1999 and reaffirmed this population goal in 2007 based on prey availability and human population density; and

WHEREAS, currently, the Wisconsin DNR has plans to review and revise the previous wolf management plan; and

WHEREAS, although gray wolves ~~are~~ were delisted from the federal endangered species list as of January 2021, but were recently added in early February, 2022, the wolf population continues to increase with a projected population of 1,034 in 2020 which has resulted in livestock predation, threats to human safety and other animals, reduced hunting opportunities, and compromised agricultural operations; and

WHEREAS, Clark County supports a wolf population management plan with a population goal of 350 or less as supported by several counties as well as interested organizations throughout the state (i.e. Wisconsin Farm Bureau and Wisconsin Wildlife Federation); and

WHEREAS, in addition to establishing a management plan for the wolf population, another management control the Wisconsin DNR uses in an effort to address depredation by wolves is to relocate problem wolves to other counties in the state; and

WHEREAS, considering Clark County has a large county forest with many agricultural operations, Clark County is concerned that the relocation of problem wolves in the county would significantly impact recreational opportunities and agricultural operations.

NOW, THEREFORE BE IT RESOLVED, the Clark County Board of Supervisors hereby supports a statewide gray wolf population goal of 350 or less as part of Wisconsin DNR's wolf management plan along with meaningful controls to achieve wolf population goals.

BE IT FURTHER RESOLVED, the Clark County Board of Supervisors hereby opposes the Wisconsin DNR from relocating problem wolves into Clark County from other counties and/or states.

BE IT FURTHER RESOLVED, that the County Clerk shall mail copies of this resolution to Governor Evers, the state legislators for Clark County, the Secretary of the DNR, DNR Wildlife Management staff, and the Wisconsin Counties Association for consideration.

RESOLUTION 2022-02

RESOLUTION CONCERNING WISCONSIN WOLF POPULATION GOAL TO THE WISCONSIN DEPARTMENT OF NATURAL RESOURCES WOLF MANAGEMENT PLAN

TO THE HONORABLE SUPERVISORS OF THE COUNTY BOARD OF THE COUNTY OF FLORENCE:

Whereas, the Wisconsin Department of Natural Resources (WDNR) established a wolf population goal of 350 animals in 1999, and reaffirmed this population goal in 2007, based on prey availability and human population density; and

Whereas, the WDNR plans to review and revise the previous wolf management plan, adopted in 1999 and reviewed and revised in 2007; and

Whereas, the Wisconsin Wildlife Federation and Wisconsin Farm Bureau, Wisconsin Conservation Congress (2011, 2013, 2021), officially support a Wisconsin Wolf population goal of 350 or less; and

Whereas, thirty-six (36) county boards, half the county boards in Wisconsin, from north to south, have passed resolutions that recommend a Wisconsin wolf population goal of 350 or less; and

Whereas, Wisconsin's residents have experienced depredations and threatening incidents involving wolves, including 107 officially listed conflicts in 2021; and

Whereas, the high predator population, in particular wolves, has resulted in the reduction of the deer population where wolves are plentiful, reduced hunting opportunities, curtailed livestock and pleasure horse activities, and are a danger to pets and people.

Now, THEREFORE, BE IT RESOLVED that the Florence County Board of Supervisors advises that Wisconsin approve a wolf population goal of 350 or less in the next Wisconsin Wolf Management Plan.

BE IT FURTHER RESOLVED that the Florence County Board of Supervisors encourages the WDNR to include elected officials from counties with high wolf conflicts in the DNR Wolf Advisory Committee.

BE IT FURTHER RESOLVED that the Florence County Board of Supervisors requests that WDNR and other partners implement meaningful population controls in the Wisconsin Wolf Management Plan.

BE IT FURTHER RESOLVED that the Florence County Board of Supervisors requests that WDNR not relocate problem wolves from other counties in the state into Florence County.

BE IT FURTHER RESOLVED that the Clerk shall forward this resolution to the offices of the Wisconsin Governor, Secretary of the WDNR, Preston Cole, Secretary of DATCP, Randy Romanski, and state and federal legislators who represent Florence County. When the WDNR public comments period for the revised Wolf Management Plan is announced, the resolution will be sent to the designated contact determined by WDNR.

Adopted January 18, 2022
I hereby certify that the foregoing resolution was duly adopted by the Florence County Board of Supervisors at a legal meeting on the 18th day of January, 2022.

RESOLUTION
103-2021

Resolution offered by the Forest County Board Chairperson:

WHEREAS, the Wisconsin Department of Natural Resources (WI DNR) established a wolf population goal of 350 animals in 1999 based on State wildlife and prey populations, State population density, and the severe decline in wildlife and prey populations throughout the State in the intervening years; and

WHEREAS, the WI DNR has not provided meaningful wolf population control in any of its management efforts; and

WHEREAS, Forest County residents have experienced a reduction in the number of wild game being hunted because of the large wolf population and residents have concerns regarding threatening incidents involving wolves; and

WHEREAS, the high predator population, in particular wolves, has resulted in the reduction of deer population, hunting opportunities, and livestock, and has made pleasure horse riding dangerous as well as presenting a danger to pets and people; and

NOW, THEREFORE, BE IT RESOLVED, that the Forest County Board of Supervisors advises that Wisconsin continue the wolf population goal of 350 or preferably less in the next revision of the Wisconsin Wolf Plan; and

BE IT FURTHER RESOLVED, that the Forest County Board of Supervisors requests that the Wisconsin DNR and other partners implement meaningful population controls in the next Wisconsin Wolf Plan to bring the wolf population to goal levels or below.

I, County Clerk, in and for the said County of Forest, State of Wisconsin, do hereby certify that the foregoing is a true and correct copy of a Resolution adopted by the County Board of Supervisors of Forest County, Wisconsin, in legal session on the 21 day of December, 2021.

Dated this 21 day of December, 2021.

Nora Matuszewski, Forest County Clerk
Erin Mayer, Forest County Deputy Clerk

RESOLUTION: #34-14
Grant County Wolf Control Resolution
7-21-15

Whereas the WI DNR established a wolf goal of 350 (minimum overwinter count) animals in 1999, and reaffirmed this minimum overwinter count goal in 2007, based on prey availability and human population density, and nothing has happened to increase prey availability or decrease human density in the intervening years, and

Whereas the WI DNR plans to review and revise the previous wolf management plan, adopted in 1999 and revised in 2007.

Whereas the Wisconsin Wildlife Federation and WI Farm Bureau have officially approved a WI wolf goal of 350 or less.

Whereas the Wisconsin Conservation Congress Spring Hearings (2011) overwhelmingly supported a WI wolf minimum overwinter count goal of 350 or less.

Whereas twenty (30) county boards in northern and west central Wisconsin have passed resolutions that recommend a wolf population goal of 350 (7) or 350 or less (22), or 50 or less (1),

Whereas Wisconsin's residents have experienced depredations and threatening incidents involving wolves, including 81 incidents to animals and 6 threats to human safety in 2013, occurring in 21 counties, and

Whereas the high predator population, in particular wolves, has resulted in the reduction of the deer population where wolves are plentiful, reduced hunting opportunities, curtailed livestock and pleasure horse activities, and are a danger to pets and people,

Therefore be it resolved that the Grant County Board of Supervisors advises that Wisconsin approve a wolf overwinter maximum count goal of 350 or less in the next revision of the Wisconsin Wolf Plan, and

Be it further resolved that the Grant County Board of Supervisors requests that the Wisconsin DNR and other partners implement meaningful population controls in the next Wisconsin Wolf Plan to bring the wolf maximum overwinter count to goal levels, and

Be it further resolved that the Grant County Board of Supervisors requests that the WI DNR not relocate wolves that have caused problems in Wisconsin or other areas into any county in Wisconsin.

Respectfully submitted to the Administrative Committee for their recommendation this 14th day of July, 2015.

/s/ Robert C. Keeney, Chair	/s/ Mark Stead, Vice Chair
/s/ Roger Guthrie, Secretary	/s/ John Patcle
/s/ Dale Hood	/s/ Robert Scallon

Vacant Position

Respectfully submitted to the Grant County Board of Supervisors for their approval on this 21st day of July, 2015.

/s/ Robert C. Keeney, Chair /s/ Linda K. Gebhard, County Clerk

ATTEST: I Linda K. Gebhard, Grant County Clerk, do certify that Resolution #34-14 Grant County Wolf Control was approved by the Grant County Board of Supervisors at a meeting held on July 21, 2015.

RESOLUTION 3025

RESOLUTION FROM IRON COUNTY CONCERNING WISCONSIN WOLF POPULATION GOAL TO THE WISCONSIN DEPARTMENT OF NATURAL RESOURCES WOLF MANAGEMENT PLAN

WHEREAS, the Wisconsin Department of Natural Resources (WDNR) established a wolf population goal of 350 animals in 1999, and reaffirmed this population goal in 2007, based on prey availability and human population density; and

WHEREAS, the WDNR plans to review and revise the previous wolf management plan, adopted in 1999 and reviewed and revised in 2007; and

WHEREAS, the Wisconsin Wildlife Federation and Wisconsin Farm Bureau, Wisconsin Conservation Congress (2011, 2013, 2021), officially support a Wisconsin Wolf population goal of 350 or less; and

WHEREAS, thirty-six (36) county boards, half the county boards in Wisconsin, from north to south, have passed resolutions that recommend a Wisconsin wolf population goal of 350 or less; and

WHEREAS, Wisconsin's residents have experienced depredations and threatening incidents involving wolves, including 107 officially listed conflicts in 2021; and

WHEREAS, the high predator population, in particular wolves, has resulted in the reduction of the deer population where wolves are plentiful, reduced hunting opportunities, curtailed livestock and pleasure horse activities, and are a danger to pets and people.

NOW, THEREFORE, BE IT RESOLVED that the Iron County Board of Supervisors advises that Wisconsin approve a wolf population goal of 350 or less in the next Wisconsin Management Plan.

BE IT FURTHER RESOLVED that the Iron County Board of Supervisors encourages the WDNR to include elected officials from counties with high wolf conflicts in the DNR Wolf Advisory Committee.

BE IT FURTHER RESOLVED that the Iron County Board of Supervisors requests the WDNR and other partners implement meaningful population controls in the Wisconsin Management Plan.

BE IT FURTHER RESOLVED that the Iron County Board of Supervisors requests that WDNR not relocate problem wolves from other counties in the state into Iron County.

BE IT FURTHER RESOLVED that the Clerk shall forward this resolution to the offices of the Wisconsin Governor, Secretary of the WDNR, Preston Cole, Secretary of DATCP, Randy Romanowski, and state and federal legislators who represent Iron County. When the WDNR public comments period for the revised Wolf Management Plan is announced, the resolution will be sent to the designated contact determined by WDNR.

Resolution adopted this 22nd day of February, 2022 by the Iron County Board of Supervisors.

ORIGINAL

RESOLUTION 03-01-2022

RE: Jackson County Wolf Resolution

WHEREAS, the Wisconsin Department of Natural Resources established a wolf population goal of 350 animals in 1999 based on prey availability and human population density, and nothing has happened to increase prey availability or decrease human density in the intervening years, and

WHEREAS, the WI-DNR has not provided for meaningful wolf population control in any of its management efforts, and

WHEREAS, Wisconsin's residents have experienced depredations and threatening incidents involving wolves, and

WHEREAS, the high predator population, in particular wolves, has resulted in the reduction of the deer population, reduced hunting opportunities, curtailed livestock and horses, and danger to pets and people,

WHEREAS, the State of Wisconsin has not entered as a litigant to the current case in federal court which is delaying delisting and the transfer of wolf management to WI-DNR,

THEREFORE BE IT RESOLVED, that the Jackson County Board advises the Wisconsin DNR continue the wolf population goal of 350 or less in the next revision of the Wisconsin Wolf Plan, and

BE IT FURTHER RESOLVED, that the Jackson County Board request that the WI-DNR and other partners implement meaningful population controls in the next Wisconsin Wolf Plan to bring the wolf population to goal level, and

BE IT FURTHER RESOLVED, that the Jackson County Board requests the State of Wisconsin to enter into litigation on the side of delisting of wolves from Endangered and Threatened Species status in order for the state to take over management of wolves.

BE IT FURTHER RESOLVED, that the Jackson County Board requests the US DOI, US FWS and WI DNR move ahead to delist the grey wolf in Wisconsin, as petitioned by the WI DNR, transferring management of the wolf population in Wisconsin to the State of Wisconsin.

BE IT FURTHER RESOLVED, that the Jackson County Board requests the WI DNR not relocate wolves that have caused problems in Wisconsin or other areas into any county in Wisconsin.

BE IT FURTHER RESOLVED, that the Jackson County Clerk is directed to send a copy of this resolution to Governor Evers, Secretary of the DNR Preston Cole, State Legislators, as well as wildlife management staff including Keith Warnke, Eric Lobner and Randy Johnson.

Respectfully Submitted:

RESOLUTION 81 - 21

WOLF CONTROL RESOLUTION

WHEREAS, the WI DNR established a wolf goal of 350 (minimum overwinter count) animals in 1999, and reaffirmed this minimum overwinter count goal in 2007, based on prey availability and human population density, and nothing has happened to increase prey availability or decrease human density in the intervening years; and

WHEREAS, the WI DNR plans to review and revise the previous wolf management plan, adopted in 1999 and revised in 2007 with its third attempt to revise the wolf management plan; and

WHEREAS, the Wisconsin Wildlife Federation and Wisconsin Farm Bureau have officially approved a WI wolf goal of 350 or less; and

WHEREAS, the Wisconsin Conservation Congress Spring Hearings in 2011 and 2013 overwhelmingly supported a Wisconsin wolf minimum over winter count goal of 350 or less; and

WHEREAS, 36 county boards in Wisconsin have passed resolutions that recommend a wolf population goal of 350 (7 counties), or 350 or less (26), or 100 or less (1), 80 or less (1) or 50 or less (1); and

WHEREAS, Wisconsin's residents have experienced depredations and threatening incidents involving wolves, including many incidents to animals; and

WHEREAS, the high predator population, in particular wolves, has resulted in the reduction of the deer population where wolves are plentiful, reduced hunting opportunities, curtailed livestock and pleasure horse activities, and are a danger to pets and people; and

NOW, THEREFORE, BE IT RESOLVED, that the Lafayette County Board of Supervisors' at the recommendation of the Executive, Rules and Legislative Committee advise that Wisconsin approve a wolf overwinter minimum count goal of 80 or less in the next revision of the Wisconsin Wolf Plan; and

BE IT FURTHER RESOLVED, that the Lafayette County Board of Supervisors' request that Wisconsin DNR and other partners implement meaningful population controls in the next Wisconsin Wolf Plan to bring the wolf minimum overwinter count to goal levels; and

BE IT FURTHER RESOLVED, that the Lafayette County Board of Supervisors' request that the WI DNR not relocate wolves that have caused problems in Wisconsin or other areas into any county in Wisconsin; and

BE IT FURTHER RESOLVED, that the Lafayette County Board of Supervisors' favor management of Wisconsin's wolves by the State of Wisconsin, not the federal government.

Carla Jacobson
Lafayette County Clerk

RESOLUTION #2-2022
INTRODUCED BY: ADMINISTRATIVE COMMITTEE
INTENT: ESTABLISH AND IMPLEMENT MORE MEANINGFUL WOLF POPULATION CONTROLS IN THE NEXT WISCONSIN WOLF MANAGEMENT PLAN

WHEREAS, The Wisconsin DNR is in the process of updating our State's Wolf Management Plan, with a published timeline as follows:

February 2022

- Draft Available For Public Input: The DNR seeks public input on the initial draft of the revised wolf management plan.
- Public Information Sessions: The DNR hosts two public information sessions before preparing for a final draft of the revised wolf management plan.

March - May 2022

- The DNR revises the draft plan based on public input.

June 2022

- Final Plan Draft Presented to Natural Resources Board: The NRB reviews and considers approval of the updated wolf management plan.

WHEREAS, in 1999, the Wisconsin Department of Natural Resources (DNR) established a wolf population goal of at least 350 wolves in Wisconsin in response to a wolf population estimated at 200 wolves; and

WHEREAS, the current wolf population in Wisconsin is estimated at between 944 and 1,377 animals; and

WHEREAS, wolves are apex predators, and their prey includes large, hoofed animals such as deer, elk, and livestock; and

WHEREAS, in 2000, the total payments for wolf damages amounted to approximately $200,000; and

WHEREAS, Langlade County residents continue to experience depredation and threatening incidents involving wolves; and

WHEREAS, the Committee requests that the Wolf Management Plan be changed to reflect a goal of no more than 350 wolves in the State of Wisconsin and that the DNR implement a monitoring and management plan in support of that goal.

NOW THEREFORE, BE IT RESOLVED, that the Langlade County Board of Supervisors hereby requests the Wisconsin DNR to keep the wolf population goal for the State of Wisconsin at no more than 350 wolves in the next Wisconsin Wolf Management Plan.

BE IT FURTHER RESOLVED, that the Langlade County Board of Supervisors requests the Wisconsin DNR and other partners to implement meaningful population controls in the next Wisconsin Wolf Management Plan to bring the wolf population down to the management goal.

BE IT FURTHER RESOLVED, that the Langlade County Clerk be directed to forward a copy of this resolution to the Secretary of the Wisconsin DNR, Governor Tony Evers, and Langlade County's representatives in the Wisconsin State Senate and Assembly.

Re: Resolution Regarding Wisconsin Wolf Population Goal and Wolf Management

Administrator Samuel Jonas,

Enclosed is Resolution # R2022-02 passed by the board of the Town of Little Rice. We are formally providing input concerning the wolf population goal and wolf management in the state of Wisconsin.

Thank you for taking the time to review this resolution.

Sincerely,

Chris Sully – Clerk

RESOLUTION CONCERNING WISCONSIN WOLF POPULATION GOAL TO THE WISCONSIN DEPARTMENT OF NATURAL RESOURCES WOLF MANAGEMENT PLAN

TOWN OF LITTLE RICE
ONEIDA COUNTY, WISCONSIN
3737 COUNTY ROAD Y – TOMAHAWK, WI 54487

RESOLUTION # R2022-02

Whereas, the Wisconsin Department of Natural Resources (WDNR) established a wolf population goal of 350 animals in 1999, and reaffirmed this population goal in 2007, based on prey availability and human population density; and

Whereas, the WDNR plans to review and revise the previous wolf management plan, adopted in 1999 and reviewed and revised in 2007; and

Whereas, the Wisconsin Wildlife Federation and Wisconsin Farm Bureau, Wisconsin Conservation Congress (2011, 2013, 2021), officially support a Wisconsin Wolf population goal of 350 or fewer and

Whereas, thirty-six (36) county boards, half the county boards in Wisconsin, from north to south, have passed resolutions that recommend a Wisconsin wolf population goal of 350 or fewer; and

Whereas, The Town of Little Rice, Oneida County, Wisconsin is dissatisfied with actions and inactions by the Department of Natural Resources and the US Fish and Wildlife service in Wisconsin to Control wolf numbers at the previously determined goal that recommended a Wisconsin wolf population goal of 350 or fewer; and

Whereas, rural taxpayers and residents of Northern Wisconsin counties have been underrepresented and discriminated against in previous wolf management plans. Additionally, these same Wisconsin residents have experienced depredations and threatening incidents involving wolves, including 107 officially listed conflicts in 2021 and many additional incidents go unreported as the underrepresented, discriminated against taxpayers and residents have no other practical alternative measures or protection; and

Whereas, there has been no meaningful long term or short-term protection by other government agencies to protect rural underrepresented, discriminated against residents and taxpayers from depredation, threats and damage when wolf numbers are radically above goal; and

Whereas, as well as wolf population control, there should be meaningful protection measures provided such as fencing for vulnerable livestock and other property, farming and all other vulnerable outdoor activities etc. (like Wisconsin's fence law) paid by agencies required to manage the wolf numbers to help protect property owners and rural underrepresented, discriminated against residents and taxpayers from impacts of wolves when identified on their property when control measures are not utilized; and

Whereas wolves are apex predators and other, even lesser, predators such as bear, bobcats, coyotes, foxes, weasels, etc. are regulated and managed within biologically and ecologically sound population levels while wolves are not; and

Whereas, the high predator population, in particular wolves, has resulted in the reduction of the deer population where wolves are plentiful, reduced land values, and recreational opportunities in northern Wisconsin, reduced hunting opportunities, curtailed livestock and pleasure activities such as horse and dog exercise and training, and are a danger to other domestic animals, livestock and people.

Now, THEREFORE, BE IT RESOLVED that the Town of Little Rice, Oneida County, Wisconsin advises that the appropriate parties with proper authority approve a wolf population goal of 350 or fewer adult wolves at least one year old (not including pups of the year) in the next Wisconsin Wolf Management Plan.

BE IT FURTHER RESOLVED that the management plan include provisions for any and all individuals, entities, organizations, etc. who deliberately and willfully choose to participate in management activities such as claiming wolf kill permits, but intentionally and willfully choosing not to exercise those privileges, be required to forfeit a fee of at least $5000 per unexercised permit to be remitted into a fund to be used to reimburse for wolf inflicted damages (e.g. depredation of livestock, domestic animals, hunting dogs, etc.) and/or wolf damage mitigation efforts.

BE IT FURTHER RESOLVED that the Little Rice Town Board, Oneida County, Wisconsin encourages the Wisconsin Department of Natural Resources (WDNR) to include elected officials from counties with high wolf conflicts in the DNR Wolf Advisory Committee.

BE IT FURTHER RESOLVED that the Little Rice Town Board, Oneida County, Wisconsin requests that the WDNR and other partners implement meaningful population controls in the Wisconsin Wolf Management Plan.

BE IT FURTHER RESOLVED that the Little Rice Town Board, Oneida County, Wisconsin requests that WDNR not relocate problem wolves from other counties in the state into the Town of Little Rice, Oneida County or adjacent Counties. If this request cannot be adhered to, the Town of Little Rice, Oneida County, Wisconsin then further requests that problem wolves be relocated equally and equitably to all other counties, towns, cities as well as other public lands such as town, county and state forests, etc. throughout the State of Wisconsin.

BE IT FURTHER RESOLVED that shortly following the time the WDNR public comments period for the revised Wolf Management Plan is announced, the resolution will be sent to the designated contacts determined by WDNR.

Adopted this 27th day of September, 2022.

Chairman Town of Little Rice

Town Chair, Steve Margitan

Town Supervisor, Theodore Albright

Town Supervisor, James Treu

I hereby certify that the foregoing resolution was duly adopted by the Town of Little Rice at a legal meeting on the 27th day of September 2022

Town Clerk, Christine Sully

Resolution #R-70-14
To encourage a wolf population of 350 animals in the Wisconsin Wolf Plan

WHEREAS the Wisconsin Department of Natural Resources (WI DNR) established a wolf population goal of 350 animals in 1999, and reaffirmed this population goal in 2007, based on prey availability and human population density, and nothing has happened to increase prey availability or decrease human density in the intervening years; and

WHEREAS the WI DNR plans to review and revise the previous wolf management plan, adopted in 1999 and revised in 2007; and

WHEREAS the Wisconsin Wildlife Federation and Wisconsin Farm Bureau have officially approved a Wisconsin wolf goal of 350 or less; and

WHEREAS the Wisconsin Conservation Congress Spring Hearings (2011) overwhelmingly supported a Wisconsin wolf population goal of 350 or less; and

WHEREAS twenty (22) county boards in northern and west central Wisconsin have passed resolutions that recommend a wolf population goal of 350 (5) or 350 or less (17); and

WHEREAS Wisconsin's residents have experienced depredations and threatening incidents involving wolves, including 81 incidents to animals and 6 threats to human safety in 2013, occurring in 21 counties; and

WHEREAS the high predator population, in particular wolves, has resulted in the reduction of the deer population where wolves are plentiful, reduced hunting opportunities, curtailed livestock and pleasure horse activities, and are a danger to pets and people; and

WHEREAS the Land Conservation and Zoning Committee passed a motion in support of a wolf population goal of 350 at its October 7, 2014 meeting and forwarded this recommendation to the Environmental Resources Committee; and

WHEREAS the Environmental Resources Committee passed a motion in support of a wolf population goal of 350 at its October 8, 2014 meeting.

NOW THEREFORE BE IT RESOLVED that the Marathon County Board of Supervisors advises that Wisconsin approve a wolf population goal of 350 in the next revision of the Wisconsin Wolf Plan; and

BE IT FURTHER RESOLVED that the Marathon County Board of Supervisors requests that the WI DNR and other partners implement meaningful population controls in the next Wisconsin Wolf Plan to bring the wolf population to goal levels; and

BE IT FURTHER RESOLVED that the Marathon County Board of Supervisors requests that the WI DNR not relocate wolves that have caused problems in Wisconsin or other areas into any county in Wisconsin.

NOW, THEREFORE, BE IT RESOLVED that the Marquette County Board of Supervisors advises that Wisconsin approve a wolf population goal of 350 or less in the next Wisconsin Wolf Management Plan.

BE IT FURTHER RESOLVED that the Marquette County Board of Supervisors encourages the WDNR to include elected officials from counties with high wolf conflicts in the DNR Wolf Advisory Committee.

BE IT FURTHER RESOLVED that the Marquette County Board of Supervisors requests that WDNR and other partners implement meaningful population controls in the Wisconsin Wolf Management Plan.

BE IT FURTHER RESOLVED that the Marquette County Board of Supervisors requests that WDNR not relocate problem wolves from other counties in the state into Marquette County.

BE IT FURTHER RESOLVED that the Clerk shall forward this resolution to the offices of the Wisconsin Governor, Secretary of the WDNR, Preston Cole, Secretary of DATCP, Randy Romanski, and state and federal legislators who represent Marquette County. When the WDNR public comments period for the revised Wolf Management Plan is announced, the resolution will be sent to the designated contact determined by WDNR.

RESOLUTION # 44-2022

Resolution to support maintaining the Wisconsin Grey Wolf population at 350 animals as set by the Wisconsin Department of Natural Resources (WDNR) Wolf Management Plan.

Resolution approved for presentation to the Oneida County Board by the Supervisors of the Forestry, Land and Recreation Committee

Resolved by the Board of Supervisors of Oneida County, Wisconsin:

WHEREAS, the Wisconsin Department of Natural Resources established a wolf population goal of 350 animals in 1999, and reaffirmed this population goal in 2007, based on prey availability and human population density, and;

WHEREAS, the WDNR plans to review and revise the previous wolf management plan, adopted in 1999 and reviewed and revised in 2007, and;

WHEREAS, the Wisconsin Wildlife Federation and Wisconsin Farm Bureau, Wisconsin Conservation Congress (2011, 2013, 2021), officially support a Wisconsin Wolf population goal of 350 or less, and;

WHEREAS, , thirty-six (36) county boards, half the county boards in Wisconsin, from north to south, have passed resolutions that recommend a Wisconsin wolf population goal of 350 or less; and

WHEREAS, Wisconsin's residents have experienced depredations and threatening incidents involving wolves, including 107 officially listed conflicts in 2021, and;

WHEREAS, the high predator population, in particular wolves, has resulted in the reduction of the deer population where wolves are plentiful, reduced hunting opportunities, curtailed livestock and pleasure horse activities, and are a danger to pets and people, and;

THEREFORE, BE IT RESOLVED, that the Oneida County Board of Supervisors advises that Wisconsin approve a wolf population goal of 350 or less in the next Wisconsin Wolf Management Plan.

BE IT FURTHER RESOLVED, that the Oneida County Board of Supervisors encourages the WDNR to include elected officials from counties with high wolf conflicts in the DNR Wolf Advisory Committee, and;

BE IT FURTHER RESOLVED, that the Oneida County Board of Supervisors requests that WDNR and other partners implement meaningful population controls in the Wisconsin Wolf Management Plan, and;

BE IF FURTHER RESOLVED, that the Oneida County Board of Supervisors requests that WDNR not relocate problem wolves from other counties in the state into Oneida County.

BE IF FURTHER RESOLVED, that the Clerk shall forward this resolution to the offices of the Wisconsin Governor, Secretary of the WDNR, Secretary of DATCP, and state and federal legislators who represent Oneida County. When the WDNR public comments period for the revised Wolf Management Plan is announced, the resolution will be sent to the designated contact determined by WDNR.

Motion by Winkler to amend line 35 in Resolution #44-2022 to strike the words "goal of 350 or less: and replace with the word "Standard"

Seconded by Schreier

OUTAGAMIE COUNTY BOARD MEETING
MAY 23, 2017

RESOLUTION NO. 10—2017-18
Supervisor Suprise moved, seconded by Supervisor Croatt, for adoption.

RESOLUTION NO. 10—2017-18 IS ADOPTED.

RESOLUTION NO.: 10—2017-18

TO THE HONORABLE, THE OUTAGAMIE COUNTY BOARD OF SUPERVISORS

LADIES AND GENTLEMEN: ***MAJORITY***

The Wisconsin Department of Natural Resources (WDNR) established a wolf goal of 350 (minimum overwinter count) animals in 1999, and reaffirmed this minimum overwinter count goal in 2007, based on prey availability and human population density, and nothing has happened to increase prey availability or decrease human density in the intervening years.

The WDNR plans to review and revise the previous wolf management plan adopted in 1999 and revised in 2007. The Wisconsin Wildlife Federation and Wisconsin Farm Bureau have officially approved a Wisconsin wolf goal of 350 or less. Thirty-four Wisconsin county boards have passed resolutions: Seven are recommending a wolf population goal of 350; 24 are recommending a goal of 350 or less; one a goal of 50 or less; one a goal of 100 or less; and one a goal of 80 or less.

Wisconsin's residents have experienced depredations and threatening incidents involving wolves, including 97 incidents to animals in 2016, occurring in 23 counties. The high predator population, wolves in particular, has resulted in the reduction of the deer population where wolves are plentiful, reduced hunting opportunities, curtailed livestock and pleasure horse activities, and are a danger to pets and people.

This resolution recommends a wolf overwinter minimum count goal of 350 or less in the next revision of the Wisconsin Wolf Plan and requests that the WDNR and other partners implement meaningful population controls in the next Wisconsin Wolf Plan to bring the wolf minimum overwinter count to goal levels. This resolution further requests that the WDNR not relocate wolves that have caused problems in Wisconsin or other areas into any county in Wisconsin. The Outagamie County Board favors management of Wisconsin's wolves by the State of Wisconsin, not the federal government.

NOW THEREFORE, the undersigned members of the Agriculture, Extension Education, Land Conservation & Zoning Committee recommend adoption of the following resolution.

BE IT RESOLVED, that the Outagamie County Board of Supervisors does recommend a wolf overwinter minimum count goal of 350 or less in the next revision of the Wisconsin Wolf Plan and requests that the WDNR and other partners implement meaningful population controls in the next Wisconsin Wolf Plan to bring the wolf minimum overwinter count to goal levels, and

BE IT FURTHER RESOLVED, that the Outagamie County Board of Supervisors request that the WDNR not relocate wolves that have caused problems in Wisconsin or other areas into any county in Wisconsin and the Outagamie County Board favors management of Wisconsin's wolves by the State of Wisconsin, not the federal government, and

BE IT FINALLY RESOLVED, that the Outagamie County Clerk be directed to forward a copy of this resolution to the Outagamie County Land Conservationist, Cathy Stepp, DNR Secretary, DATCP Secretary, and the Outagamie County Lobbyist for distribution to Governor Walker and state and federal legislators.

Dated this 23rd day of May 2017

Respectfully Submitted,

Resolution No. 01-22

RESOLUTION CONCERNING WISCONSIN WOLF POPULATION AND REQUESTING REVISION TO WISCONSIN DEPARTMENT OF NATURAL RESOURCES (WDNR) WOLF MANAGEMENT PLAN

TO THE POLK COUNTY BOARD OF SUPERVISORS:

WHEREAS, the WDNR established a wolf population goal of 350 animals in 1999 and reaffirmed this population goal in 2007, based upon prey availability and human population density and nothing has happened to increase prey availability or decrease human density in the intervening years; and

WHEREAS, the WDNR plans to review and revise the previous wolf management plans; and

WHEREAS, the Wisconsin Wildlife Federation and the Wisconsin Farm Bureau have officially approved a Wisconsin wolf population goal of 350 or less; and

WHEREAS, the Wisconsin Conservation Congress (WCC) Spring Hearings (2011 & 2013) overwhelmingly supported a Wisconsin wolf population goal of 350 or less(confirmed by the Executive Committee of the WCC in 2021); and

WHEREAS, thirty six (36) county boards from northern to southern Wisconsin have passed resolutions that recommend a Wisconsin wolf population goal of 350 or less; and

WHEREAS, Wisconsin's residents have experienced depredations and threatening incidents involving wolves, including 104 incidents in 2021; and

WHEREAS, the high predator population, wolves in particular, has reduced of the deer population, diminished hunting opportunities, curtailed livestock and pleasure horse activities, and caused danger to pets and people.

NOW, THEREFORE, BE IT RESOLVED, that the Polk County Board of Supervisors urges Wisconsin to approve a wolf population goal of 350 or less in the next revision of the Wisconsin Wolf Management Plan.

BE IT FURTHER RESOLVED, that the Polk County Board of Supervisors encourages the Wisconsin Counties Association and the Wisconsin Towns Association to work with the WDNR to place an elected official from one of the counties with the largest wolf depredation claims to the DNR Wolf Advisory Committee.

BE IT FURTHER RESOLVED, that the Polk County Board of Supervisors requests that the WDNR and other partners implement meaningful population controls in the next Wisconsin Wolf Management Plan to bring the wolf population to goal levels.

BE IT FURTHER RESOLVED, that the Polk County Supervisors encourage the expired chair position of the Natural Resources Board to the WDNR step down and let the currently appointed chair resume duties.

BE IT FURTHER RESOLVED, that the Clerk forward a copy of this Resolution to the offices of Governor Tony Evers; Preston Cole, WDNR Secretary; Randy Romanski, WDATCP Secretary; and the State and Federal legislators who represent the People of Polk County.

SUBMITTED BY:

Brad Olson

Amendment to Resolution 01-22 as approved by the County Board of Supervisors on 1/18/2022, has been incorporated in this document.

Resolution 11-22
Wisconsin Wolf Population Goal
Wisconsin Department of Natural Resources Wolf Management Plan

WHEREAS, the Wisconsin Department of Natural Resources (WDNR) established a wolf population goal of 350 animals in 1999, and reaffirmed this population goal in 2007, based on prey availability and human population density; and

WHEREAS, the WDNR plans to review and revise the previous wolf management plan, adopted in 1999 and reviewed and revised in 2007; and

WHEREAS, the Wisconsin Wildlife Federation and Wisconsin Farm Bureau, Wisconsin Conservation Congress (2011, 2013, 2021), officially support a Wisconsin Wolf population goal of 350 or less; and

WHEREAS, thirty-six (36) county boards, half the county boards in Wisconsin, from north to south, have passed resolutions that recommend a Wisconsin wolf population goal of 350 or less; and

WHEREAS, Wisconsin's residents have experienced depredations and threatening incidents involving wolves, including 107 officially listed conflicts in 2021; and

WHEREAS, the high predator population, in particular wolves, has resulted in the reduction of the deer population where wolves are plentiful, reduced hunting opportunities, curtailed livestock and pleasure horse activities, and are a danger to pets and people.

NOT, THEREFORE BE IT RESOLVED that the Price County Board of Supervisors advises that Wisconsin approve a wolf population goal of 350 or less in the next Wisconsin Wolf Management Plan.

BE IT FURTHER RESOLVED that the Price County Board of Supervisors encourages the WDNR to include elected officials from counties with high wolf conflicts on the DNR Wolf Advisory Committee.

BE IT FURTHER RESOLVED that the Price County Board of Supervisors requests that the WDNR and other partners implement meaningful population controls in the Wisconsin Wolf Management Plan.

BE IT FURTHER RESOLVED that the Price County Board of Supervisors requests that WDNR not relocate problem wolves from other counties in the state into Price County.

BE IT FURTHER RESOLVED that the County Clerk shall forward this resolution to the offices of the Wisconsin Governor; Secretary of the WDNR, Preston Cole; Secretary of DATCP, Randy Romanski, and state and federal legislators who represent Price County. When the WDNR public comments period for the revised Wolf Management Plan is announced, the resolution will be sent to the designated contact determined by WDNR.

RESOLUTION NO. 17 - 45

A Resolution Recommending That The Wisconsin Department Of Natural Resources Establish A Wisconsin Wolf Plan Calling For An Over-Winter Wolf Population Of 350 Or Less.

WHEREAS in 1999 and in 2007 the Wisconsin Department of Natural Resources (DNR) established a wolf population goal of 350 wolves, and

WHEREAS limiting the wolf population to not more than 350 animals has considerable support from involved organizations and, furthermore, an excessive wolf population can have many bad effects including a reduction of the deer population, reduced hunting opportunities, a danger to livestock, reduced horse riding opportunities and a danger to pets and humans, and

WHEREAS the Land Conservation Committee has carefully considered this proposal and is presenting this Resolution to the County Board for its consideration.

NOW THEREFORE BE IT RESOLVED by the Richland County Board of Supervisors that the County Board recommends that the Wisconsin Department of Natural Resources establish a Wisconsin Wolf Plan calling for an over-winter wolf population of 350 or less and that DNR establish meaningful wolf population controls in the next Wisconsin Wolf Plan, and

BE IT FURTHER RESOLVED that Richland County hereby requests that the DNR not relocate wolves that have caused problems in Wisconsin into any county in Wisconsin and, furthermore, that Richland County favors management of Wisconsin wolves by the State of Wisconsin and not by the Federal government, and

BE IT FURTHER RESOLVED that the County Clerk shall send a copy of this Resolution to Governor Scott Walker, to DNR Secretary Cathy Stepp, to Department of Agriculture Trade and Consumer Protection Secretary Ben Brancel, and to all State legislators whose district includes any part of Richland County and to the Wisconsin Counties Association, and

BE IT FURTHER RESOLVED that this Resolution shall be effective immediately upon its passage and publication.

Certification:

I, Connie Meyer, Clerk of Rusk County, hereby certify that the above is a true and correct copy of a resolution that was adopted on the 1 day of March, 2021 by the Rusk County Board of Supervisors.

Connie Meyer
County Clerk, Rusk County

TO THE RUSK COUNTY BOARD OF SUPERVISORS

WHEREAS, the WiDNR established a wolf population goal of 350 animals in 1999 and reaffirmed this population goal in 2007, based upon prey availability and human population density; and

WHEREAS, the WiDNR plans to review and revise the previous wolf management plans; and

WHEREAS, the Wisconsin Farm Bureau and the Wisconsin Conservation Congress both approve and support a Wisconsin wolf population goal of 350 animals or less; and

WHEREAS, thirty six (36) county boards from Northern to Southern Wisconsin have passed resolutions that recommend a Wisconsin wolf population goal of 350 animals or less; and

WHEREAS, Wisconsin residents have experienced depredations and threatening incidents involving wolves, including 104 incidents in 2021; and

WHEREAS, high predator populations can contribute to reduced prey animal populations, diminished hunting opportunities, livestock depredation, and pose a danger to pets and people; and

WHEREAS, the Rusk County Board of Supervisors recognizes the importance of maintaining a balanced population of wolves in Wisconsin.

NOW, THEREFORE, BE IT RESOLVED, that the Rusk County Board of Supervisors urges WiDNR to consider a wolf population goal of 350 or less in the next revision of the Wisconsin Wolf Management Plan; and

BE IT FURTHER RESOLVED, that the Rusk County Board of Supervisors encourages the Wisconsin Counties Association and the Wisconsin Towns Association to work with the WiDNR to place an elected official from one of the counties with the largest wolf depredation claims to the DNR Wolf Advisory Committee; and

BE IT FURTHER RESOLVED, that the Rusk County Board of Supervisors requests that the WiDNR and other partners implement meaningful and accurate population controls in the next Wisconsin Wolf Management Plan; and

BE IT FURTHER RESOLVED, that the Clerk forward a copy of this Resolution to the offices of Governor Tony Evers; Preston Cole, WiDNR Secretary; Randy Romanski, WiDATCP Secretary; and the State and Federal legislators who represent the People of Rusk County.

AMENDMENT: (last paragraph)

Docket No. 2010-3-35

RESOLUTION NO. 26

A RESOLUTION REQUESTING THE DELISTING OF THE GRAY WOLF AS AN ENDANGERED SPECIES IN WISCONSIN.

WHEREAS, the gray wolf in Wisconsin is currently listed as an endangered species by the Federal Government; and

WHEREAS, the status of listed as "endangered" negates the ability of the State of Wisconsin to manage the wolf population and attempt to control depredation of livestock and pets by problem wolves; and

WHEREAS, the target population, set by the Federal Government, for delisting the wolf in Wisconsin and Michigan, must be greater than 100 animals sustained for a period of five years; and

WHEREAS, the Wisconsin Department of Natural Resources (WDNR) places the Wisconsin 2010 late winter population estimate at 720, said population having been in excess of 350 since 2003, with wolves occupying virtually all suitable habitat in Wisconsin; and

WHEREAS, the wolf population in Wisconsin has exceeded the above specified target population for delisting; and

WHEREAS, there is no reason to believe the wolf remains endangered or threatened in Wisconsin; and

WHEREAS, the WDNR has submitted a petition to the U.S. Department of Interior (USDOI) and the U.S. Fish and Wildlife Services (USFWS) to delist the gray wolf in Wisconsin; and

NOW THEREFORE, BE IT RESOLVED, that the Taylor County Board of Supervisors duly assembled on this 3rd day of August, 2010, requests that the USDOI and the USFWS move ahead to delist the gray wolf in Wisconsin, as petitioned by the WDNR, transferring management of the wolf population in Wisconsin the State of Wisconsin, and

BE IT FURTHER RESOLVED, that the Taylor County Board of Supervisors requests that the State of Wisconsin use all its legal resources to pursue the delisting of the gray wolf in Wisconsin from the Federal Endangered and Threatened Species Lists and transfer wolf management in the State of Wisconsin to the State of Wisconsin.

BE IT FURTHER RESOLVED, that the Taylor County Board of Supervisors requests that the WDNR consider, in its revision of the Wolf Management Plan,

population goals that reflect changes in the amount of human activity and development in areas that were viewed as suitable habitat in 1995, which resulted in a population goal of 350 animals as established in the 1999 Wisconsin Wolf Management Plan.

BE IT FURTHER RESOLVED, that the Taylor County Board of Supervisors requests that the WDNR and its partners implement much needed population controls to bring the wolf population to goal levels when formulating the next Wisconsin Wolf Management Plan.

BE IT FURTHER RESOLVED, that the Taylor County Board of Supervisors directs the Taylor County Clerk to forward copies of this resolution to: Secretary of the Interior, Ken Salazar, U.S. Fish & Wildlife Service acting director, Rowan Gould, Senators, Russ Feingold & Herb Kohl, Representatives, Ron Kind & David Obey, Governor, Jim Doyle, State Senators, Russ Decker & ~~Scott Suder~~ and Secretary of WDNR, Matthew Frank.

INTENT & SYNOPSIS: To support a statewide wolf population management goal of 350 animals ~~or less~~.

WHEREAS, the Wisconsin Department of Natural Resources established a wolf population goal of 350 animals or less in 1999 based on prey availability and human population density, and nothing has happened to increase prey availability or decrease human population density in the intervening years, and

WHEREAS, the WI DNR plans to review and revise the previous wolf management plan, adopted in 1999 and revised in 2007, and

WHEREAS, the Wisconsin Wildlife Federation and WI Farm Bureau have officially approved a WI wolf population goal of 350, and

WHEREAS, the Wisconsin Conservation Congress Spring Hearings (2011) overwhelmingly supported a WI wolf population goal of 350 or less, and

WHEREAS, eighteen (18) county boards in northern and west central Wisconsin have passed resolutions that recommend a wolf population goal of 350 (4) or 350 or less (14), and

WHEREAS, Wisconsin residents have experienced depredations and threatening incidents involving wolves, and

WHEREAS, the high predator population, in particular wolves, has resulted in the reduction of the deer population, reduced hunting opportunities, curtailed livestock and pleasure horse activities, and are a danger to pets and people,

THEREFORE BE IT RESOLVED, that the Wood County Board advises that Wisconsin continue the wolf population goal of 350 ~~or less~~ in the next revision of the Wisconsin Wolf Plan, and

BE IT FURTHER RESOLVED, that the Wood County Board requests that the Wisconsin DNR and other partners implement meaningful population controls in the next Wisconsin Wolf Plan to bring the wolf population to goal levels, and

BE IT FURTHER RESOLVED, that the Wood County Board requests that the WI DNR not relocate wolves that have caused problems in Wisconsin or other areas into any county in Wisconsin.

***Motion by Murphy/Breu to adopt Resolution13-8-7. Motion by Machon/Clendenning to strike the words "or less" in regards to the management goal of 350 animals. Motion carried. Re: Comments from Center for Biological Diversity

To Whom It May Concern:

I write to provide comments on the draft Wisconsin Wolf Management Plan on behalf of the Center for Biological Diversity ("Center"), as well as our thousands of Wisconsin members and supporters. The Center is a national, nonprofit conservation organization with more than 1.7 million members and online activists dedicated to the protection of endangered species and wild places.

To begin, I'd like to acknowledge the many improvements of this draft over the outdated plan that it will replace. In particular, the old plan's numerical goal of just 350 wolves was outdated and did not reflect the ecological importance of wolves[1] or the broad, ongoing public support for wolves in the state.[2]

Additionally, the draft plan takes steps to recognize the importance of wolves to sovereign Tribal nations by including a buffer around reservations. Killing wolves for stepping over an invisible political boundary would interfere with the Tribal nations' ability to conserve their wolves consistent with their cultural and other values.

[1] Beschta, R. L. & Ripple, W. J. Can large carnivores change streams via a trophic cascade? Ecohydrology, 12(1): e2048 (2019), https://trophiccascades.forestry.oregonstate.edu/sites/trophic/files/Beschta2019_Ecohyd.pdf; Wilmers, C.C. and W.M. Getz. Gray Wolves as Climate Change Buffers in Yellowstone. Recolonizing wolves trigger a trophic cascade in Wisconsin (USA). Journal of Ecology 101: 837–845 (2013), https://besjournals.onlinelibrary.wiley.com/doi/full/10.1111/1365-2745.12095.

[2] Wisconsin DNR. Public Opinions Regarding Wolves and Wolf Management in Wisconsin (2022), https://widnr.widen.net/s/tsvfkqkh9w/pub_ea_017.

Our primary concern with the draft plan is the reliance on outdated or unreliable science to justify killing of wolves, largely to benefit a minority of livestock operators that experience conflicts with wolves. Yet recent science shows that nonlethal methods are effective:

> [N]onlethal methods of preventing depredation of livestock by large carnivores may be more effective, more defensible on ecological, legal, and wildlife-policy grounds, and more tolerated by society than lethal methods, and that total mortality rates for a large carnivore may be driven higher than previously assumed by human causes that are often underestimated.[3]

Science also shows that killing predators is costly and ineffective in the long-term:

> We reviewed literature investigating predator removal and focused on identifying successes and failures…. Predator removal appeared to only be effective for the short-term, failing in the absence of sustained predator suppression. This means predator removal was typically an ineffective and costly approach to conflicts between humans and predators.[4]

And that killing wolves sometimes exacerbates the conflicts:

> Of those twelve, prevention of livestock predation was demonstrated in six tests (four non-lethal and two lethal), whereas counterintuitive increases in predation were shown in two tests (zero non-lethal and two lethal); the remaining four (one non-lethal and three lethal) showed no effect on predation.[5]

As such, the final plan should require livestock operators to use of nonlethal methods to prevent conflict with wolves prior to any allowance for wolf killing or financial compensation.

Next, I wish to emphasize that trophy hunting of wolves is inconsistent with the values of most people in Wisconsin. At the state's public attitudes survey demonstrates, most respondents

indicated opposition to hounds (64%) and traps (70%) and hold feelings that hunting wolves is unnecessary (62%) or culturally offensive to Native American tribes (57%).[6] At a minimum, the new plan should prohibit use of the cruelest methods of killing wolves, including trapping and hounding. The plan should be updated every five years to ensure consistency with emerging science and evolving public values.

Finally, killing wolves reduces their ability to provide ecological services of incalculable economic value to the people of Wisconsin, such as controlling chronic wasting disease[7] and reducing collisions between deer and cars.[8] More studies that demonstrate such benefits of having wolves on the landscape should be incorporated into the final plan.

Attn: Secretary Adam Payne, Wisconsin Department of Natural Resources
Re: Draft Wolf Management Plan
Date: February 28, 2023

Dear Secretary Payne,

I write you today on behalf of the Congressional Sportsmen's Foundation (CSF) to provide comment on the draft Wisconsin Wolf Management Plan, which in its current form does not provide sufficient, data-driven mechanisms for managing the population. CSF respectfully recommends that the final version of the plan includes a target statewide population goal and a framework for management that includes hunting for when the wolf is ultimately delisted from the list of endangered species. Despite their charisma and mystery, wolves are not fundamentally different than any other wildlife species in Wisconsin, and CSF contends that it is a mistake to subject this species to a different wildlife management model.

Founded in 1989, the Congressional Sportsmen's Foundation is the informed authority across outdoor issues and serves as the primary conduit for influencing public policy. Working with the Congressional Sportsmen's Caucus (CSC), the Governors Sportsmen's Caucus (GSC), and the National Assembly of Sportsmen's Caucuses (NASC), CSF gives a voice to hunters, anglers, recreational shooters, and trappers on Capitol Hill and throughout state capitols advocating on vital outdoor issues that are the backbone of our nation's conservation legacy.

By abandoning a numeric population goal, a common practice followed by state wildlife management agencies across the country where wolf populations exist, the Wisconsin Department of Natural Resources (DNR) will not have an accurate frame of reference to evaluate whether the final version of the Wolf Management Plan is operating as intended. Wisconsin is home to roughly 1,100 wolves, which freely range in and out of Minnesota and Michigan, creating a regional population exceeding 4,000 wolves. CSF agrees that this wolf population has fully recovered and is fit to be delisted and actively managed by the individual states. However, without a statewide population goal, the DNR cannot implement management practices that aim to achieve a specific outcome, which will likely cause wolf populations to continue to grow beyond their biologic and cultural carrying capacity – negatively impacting the very wolves this plan seeks to manage, as well as livestock such as cattle, and a variety of wildlife specifies including elk and deer. Given the current impact that the wolf population already has on Wisconsin's natural ecosystems, CSF recommends that the DNR adopt a numeric population goal that is lower than the current population of the species in the state.

Further, CSF maintains that hunting is the best means of managing wolf populations and recommends that the DNR create a framework for a science-based wolf hunting season that can be implemented upon the species' inevitable delisting. To ignore the likelihood that the wolf will be delisted before the next management plan is considered, which could be decades in the future, would fail to properly create a robust plan that uses all management practices available to the DNR.

Despite their charismatic demeanor, wolves are wildlife all the same and should be managed through the same state management practices that Wisconsin currently employs for its many wildlife species. State wildlife population management that includes hunting has produced countless success stories of species that were once extirpated from their historical ranges, including turkey, deer, and wood ducks, to name a few. Wolves should not be managed by a framework different than the other various species that occupy Wisconsin's storied landscape.

In conclusion, the Congressional Sportsmen's Foundation recommends that wolves are not granted a status that differentiates the species from other wildlife populations in Wisconsin. The draft Wolf Management Plan should be amended to implement a numeric population goal and should include a framework for achieving that numeric goal through hunting, once the wolf is inevitably removed from the endangered species list. I thank you for the opportunity to provide these comments and welcome any questions.

Sincerely,

Robert Matthews
Senior Coordinator, Great Lakes States
Congressional Sportsmen's Foundation
[redacted]

The 130+ members of the Exeland Rod & Gun Club of Exeland, Wi strongly object the Wolf Plan as currently written. Not setting a population goal, when managing any species, is not managing at all. To say "Increase, Decrease or Maintain" just pushes the problem down the road to be addressed at a later date by a different set of managers. Your plan simply passes the buck. The northern tier of counties in Wisconsin is experiencing declining deer populations and declining deer hunter numbers. The #1 reason for those declines is predation on the deer herd and lack of harvest by hunters. If the Department truly wants to increase/retain hunters, leave more deer on the landscape by reducing predator numbers. One more point - your "buffer zone" idea is a joke. Totally unnecessary. Wolf numbers are exploding without any buffers.

Al Gerber, President - Exeland Rod & Gun Club

We, the Girls Scouts of Troop 8147 of the Girl Scouts of Wisconsin - Badgerland Council, would like to put forward our comments on the DNR's Proposed Wolf Management Plan. We feel the following elements are important and should remain a part of the plan:

- Talk to people in all areas of the state about how they are impacted by the local wolf population.
- Continuously monitor local wolf populations to ensure an appropriate hunting quota, and permit hunting only when each population is healthy enough to sustain itself.
- Enforce hunting limits better and faster.

We urge you to remember that wolves are important in maintaining a healthy balance of natural resources in Wisconsin. They help keep herbivore populations at sustainable levels and also provide a food source for scavengers, both of which are important in maintaining biodiversity.

We ask you to please remember that wolves face many other challenges from humans, including loss of habitat and hunting grounds. Before people hunt the threatened wolf population we need to carefully consider the many other natural and human challenges the wolves are facing.

Thank you for your consideration,

Vivienne, Sofia, Finley, Jojo, Emma & Daphne*

A note from Troop 8147 Leaders:

This troop of 9- and 10-year-old Junior Girl Scouts voted unanimously on the Wolf Management Plan as the current issue they wanted to investigate while working towards their Democracy for Juniors badge this year. They demonstrated great interest in learning about the multiple perspectives on this issue and became very passionate about the topic. As proud troop leaders we would like to inform the government entities and officials involved in the creation and approval of this plan that the planning and decisions being made now are already being reviewed and observed by the voters and leaders of tomorrow.

Sincerely,

Vickie Eiden & Eileen Murphy

*Daphne is a younger sister Brownie level Girl Scout; while a member of a younger troop she also participates in all Troop 8147 meetings.

Wolf Management Plan Comments
101 S. Webster Street
PO Box 7921
Madison, WI 53707-7921

Submitted via email to DNRWildlifeSwitchboard@wisconsin.gov.

Dear Secretary Payne, Randy Johnson and WDNR Bureau of Wildlife Management,

On behalf of the Humane Society of the United States and our members and supporters in Wisconsin, I submit the following comments on the draft Wolf Management Plan ("draft plan").

We greatly appreciate the DNR's efforts to craft this draft plan, and the DNR's inclusion of a representative from the Humane Society of the United States on the Wolf Management Plan Committee. This draft plan offers several improvements over Wisconsin's previous plan, including a robust update to the biological and social science that will guide future wolf management. We support the recommendations to rein-in some of the harms caused by trophy hunting and trapping wolves, the removal of a numerical population management goal, and the DNR's commitment to making information about wolves transparent and easily accessible to the public. We are also encouraged by Product B1h, to Develop Wolf Conflict Mitigation Plans focused on non-lethal conflict prevention tools on farms with chronic wolf conflicts, and feel it is a step in the right direction.

However, we continue to have some concerns with the draft plan. Specifically, the Humane Society of the United States is staunchly opposed to Product C2h, to establish a season to train hounds to hunt wolves. We also feel the draft plan puts an alarming emphasis on trophy hunting and trapping wolves when they are not protected under the federal Endangered Species Act. The draft plan largely ignores or downplays the significant ecological and economic benefits wolves provide, as well as the immense harms to wolves caused by trophy hunting and trapping seasons. Additionally, a higher emphasis should be placed on non-lethal conflict prevention measures in Section 3 and Section 4, Objective B, and the final plan should include a provision to update it at least every 5-10 years, rather than suggesting that the plan is "valid until replaced."[1]

Wisconsin has a responsibility to update the wolf management plan in a way that supports a healthy, genetically diverse, and socially stable wolf population and is rooted in the best available science and Traditional Ecological Knowledge,[2] ethics and

[1] Draft plan, page xi.
[2] The Great Lakes Indian Fish and Wildlife Commission (GLIFWC) provides the following explanation of Traditional Ecological Knowledge: "There are multiple definitions of TEK and what information is categorized as such. For GLIFWC, TEK is typically recognized as a subset of the wealth of Anishinaabe

public values. As a keystone species, the benefits wolves provide ripple throughout our ecosystem and have been instrumental in restoring biological diversity.[3] While there are many scientific studies documenting the consequences of killing wolves, there is not a single one that provides a good reason to justify killing such intelligent, social animals who provide so many ecological and cultural benefits.[4] Among other recommendations that will be discussed in these comments, the final plan must meet this responsibility by including the following key changes:

- De-emphasizing wolf trophy hunting and trapping and recommending policy changes to eliminate the mandate that Wisconsin hold a trophy hunting and trapping season on wolves when they are not federally protected;
- Further discussing and emphasizing a clear prioritization of non-lethal methods for preventing conflicts with livestock; and
- Including a strong commitment to give *all* Wisconsinites a seat at the table in guiding wolf policy. Based on the 2022 public attitudes survey detailed in the draft plan, the majority of Wisconsinites clearly value wolves and want them to thrive in Wisconsin.[5] These values should be more proportionately represented in groups that have influence over wolf policy.

1. Wisconsinites value wolves

As described in Section 2 of the draft plan, Wisconsin residents value wolves. The Humane Society of the United States does have some concerns about the methodologies used to conduct the survey, including the oversampling of residents who live in areas where wolves live, and the fact that, relative to Wisconsin's population, respondents to the survey were disproportionately male, older, and self-identified as a hunter and/or a trapper. However, this survey is helpful in analyzing some of the ways attitudes toward wolves have shifted in Wisconsin since 2014. Specifically, support for a hunting and trapping season has declined by 15%, and statewide, attitudes toward wolves have grown more positive.[6]

According to the DNR's report, approximately 3 out of every 4 respondents agree that, "wolves are special animals that deserve our admiration," "predators like wolves keep nature in balance," "wolves are culturally important," and "people and wolves should be able to coexist."[7] Additionally, a whopping 80% agree that, "it is important to maintain a wolf population in Wisconsin,"[8] and most Wisconsinites do not want wolves eliminated.[9] Furthermore, based on responses regarding specific management options for wolves, the report states, "All of these statements suggest a preference among Wisconsinites statewide to reduce wolf-human conflicts via preventative approaches."[10]

Among respondents who were opposed to a wolf trophy hunting and trapping season, 70% opposed the use of traps and 64% opposed the use of hounds.[11]

In June 2021, Remington Research Group surveyed 800 Wisconsin voters about wolves.[12] Their results show that most Wisconsinites (60%) oppose the trophy hunting and trapping of wolves in Wisconsin (compared to just 24% who supported such seasons). While these results differ from the DNR's survey, it is important to again note the potential sampling bias of the DNR's survey that could influence the results of this question and that the DNR's question on this topic implied that such seasons would be necessary to "manage wolf populations" rather than being for recreation or a trophy.

The literature review of global human dimensions research from the last decade related to wolf management that is included in the draft plan similarly found that, "studies continue to find neutral to positive attitudes about wolves among the general population."[13] As the literature review discussed, current social science demonstrates that American values relating to wildlife, including wolves, are becoming increasingly rooted in an ethic of mutualism—that is that wild animals are worthy of care and compassion.[14] Countless studies and polls demonstrate that Americans oppose trophy hunting.[15] Indeed, most Americans have positive attitudes toward wolves, and those attitudes have become more positive over the past few decades.[16]

Finally, we appreciate the inclusion of written narratives from some of the federally recognized tribes in Wisconsin. We hope the perspectives and Traditional Ecological Knowledge shared in these narratives and at other points during the plan development process will be more thoroughly incorporated into the final plan.

2. Trophy hunting and trapping wolves goes against the best available science

The draft plan places an alarming emphasis on trophy hunting and trapping wolves when they are not federally protected under the Endangered Species Act. Currently, when wolves are not federally protected, they may be trophy hunted and trapped using a variety of cruel methods, including with the use of leghold traps, strangling neck snares, electronic calls, bait, and packs of radio-collared hounds.

While we understand that Act 169 mandates that Wisconsin hold such seasons, the final plan should include additional scientific information regarding the harms caused by these seasons and provide a recommendation that the statute be changed to remove this requirement or that quotas be set to zero.

Peer-reviewed studies show that trophy hunting and trapping seasons are highly detrimental to wolves.[9] Such seasons can actually decrease social tolerance for wolves, increase wolf poaching, and exacerbate conflicts with livestock.[10] While many of these arguments are referenced in the draft plan, the draft plan often downplays them or negates them with language about wolf resiliency.

A. The best available science does not support trophy hunting and trapping

The best available science does not support killing wolves and demonstrates that trophy hunting wolves causes "additive" and "super-additive" mortality, resulting in death and disruption beyond the individual killed.[17] Killing single adult wolves can result in the loss of *entire packs*, by causing the loss of dependent offspring and disrupting the pack's social structure.[18] Additive mortality can increase the total death rate of a population,[19] whereas "super-additive mortality" describes a population decline larger than expected from documented mortality. This can occur through the killing of some individuals (by humans), which then indirectly increases the risk of death for others (e.g., pack disruption) or through failures of immigration and births to compensate.[20]

Studies show that killing wolves causes especially severe super-additive-mortality effects, because their complex pack structure makes them particularly susceptible to social disruption.[21] The human-caused death of individual adult wolves harms family group cohesion and has a disproportionately large

[21] Bryan et al., 2015.

influence on population dynamics.[22] Wolves exposed to heavy hunting also experience increased stress and reproductive hormone imbalance.[23] The human-caused loss of breeding females has been shown to cause complete dissolution of social groups and abandonment of territory.[24] The human-caused loss of adults also diminishes pup survival and consequently the survival of the pack.[25]

Numerous studies have detailed the realized and potential effects of decreasing wildlife populations through legal trophy hunting and predator control on population genetics.[26] Frank et al. (2021) state that removing fit adults, "[C]an reshape sociospatial structure, genetic composition, fitness, and potentially affect evolution."[27] This is particularly concerning, because, as Ausband (2022) states, "A lack of genetic diversity can result in lower reproduction and survival and ultimately increase the probability of extinction."[28]

The genetic consequences of hunting were documented in Minnesota wolves just one year after a trophy-hunting season was implemented in 2012.[29] The observed effects included a significant increase in structuring and differentiation among subpopulations, decreased dispersal and gene flow among subpopulations, and elevated mortality of dispersing wolves.[30] These results are corroborated by similar findings in a wolf population in Alaska.[31] It is clear that even low to moderate rates of legal wolf killing are not genetically neutral and invoke harmful population-wide genetic and demographic changes that can dramatically reduce population viability, elevate extinction risk, and require multiple generations for wolf populations to recover from.[32]

B. Wolf trophy hunting and trapping increases wolf poaching

The best available science, demonstrates that relaxing wolf protection policies and/or allowing the killing of wolves for hunting, trapping, or purported livestock protection purposes can actually decrease social tolerance and increase wolf poaching.[33] Researchers demonstrate that poaching likely increases in a population as legal killing of that population is expanded.[34] Santiago-Avila et al. (2020) state:

> [W]ould-be poachers respond to the policy changes as a signal to increase their activities, possibly associated with cognitive processes relating to values (e.g., lower value of wolves in the eyes of would-be poachers), social norms (e.g., greater acceptability of poaching, or less enforcement against poaching), or perceived control (e.g., would-be poachers perceive themselves helping authorities to kill wolves).[35]

According to Liberg et al. (2012), "Because of their characteristic low densities combined with their slow rates of population growth, top predators are particularly vulnerable to effects of poaching."[36] Their study showed that approximately half (51%) of total mortality among Scandinavian wolves was caused by poaching and more than two-thirds (69%) of the total poaching was cryptic (i.e., successfully hidden from authorities). In a subsequent study, Treves et al. (2017) stated, "When one examines the percentage of individuals dying per unit time within a predator population (referred to as the hazard rate), poaching can push carnivore populations toward population crashes, at least in human-dominated landscapes."[37] In analyzing the deaths of radio-collared Wisconsin wolves that occurred between 1979 and 2012, they found that at least two-thirds of deaths were caused by humans and 39-45% of all deaths were from poaching (the authors acknowledge this figure is an underestimate). They also estimated that 80-84% of poached, unmonitored collared wolves were cryptically poached.[38]

Furthermore, a recent study analyzing monitoring data from adult, radio-collared Wisconsin wolves that was collected between 1979 and 2012 (a period during which these wolves were federally protected under the Endangered Species Act) found that reported poaching and disappearances (likely from cryptic poaching) significantly increased during certain seasons.[39] Those seasons included legal hunting for other large mammals (e.g., black bear and white-tailed deer), seasons during which it was legal to train or use hunting hounds, and seasons during which there was snow cover compared to seasons without these characteristics.[40] Specifically, the rate of poaching more than doubled during late winter to early spring, when hunting and hounding periods were over but there was still snow on the ground.[41]

[41] *Id.*

When snow cover and hunting periods overlapped from late fall to early winter, the documented poaching rate increased by 658%.[42]

Most importantly, recent research demonstrates that liberalizing legal killing (through hunting/trapping seasons or removals for purported livestock losses[43]) is likely to increase the incidence of illegal poaching of the same population.[44] In other words, the act of changing a policy to reduce or remove protections for wolves is associated with a significant decrease in potential wolf population growth rates and that decrease was independent of the number of wolves killed legally. The results of Santiago-Avila et al. (2020) suggest that when the government relaxed protections for wolves, poachers killed more wolves and concealed more evidence of their activities.[45] Their results also suggest that changes to policy that liberalize killing wolves were associated with an 85% likelihood of increasing the risk of disappearance for their studied population.[46]

C. Changes must be made to align the final plan with the best available science

The Humane Society of the United States appreciates some of the changes that have been made regarding wolf trophy hunting and trapping. As previously stated, we support the removal of a numerical population management goal. Wolf populations should not be managed for a specific number, but rather the goal should be for the state to have a self-sustaining, self-regulating and genetically diverse population that maintains connectivity with wolf populations in neighboring states and fulfills their ecological roles. We also support the delineation of Subzones 1B and 2B, which would be "designed to minimize wolf harvest in areas adjacent to large tribal reservations within wolf range which support wolf packs primarily on and adjacent these reservations."[47] We strongly recommend that the subzone limits in 1B and 2B be set at zero.

Additionally, while we remain strongly opposed to any wolf trophy hunting and trapping, we are supportive of the recommended policy changes under Objective C that aim to mitigate some of the harms caused by such seasons. Specifically, we support Products C2a and C2c, which recommend pursuing administrative rules to reduce registration time to eight hours and to issue wolf licenses that are only valid in the specific zone specified on the license. These changes will help the DNR more closely monitor how many wolves are being killed and hopefully prevent a repeat of the disastrous February 2021 season.[48]

[46] Santiago-Avila, F. J., Chappell, R. J., & Treves, A. (2020).

[47] Draft plan, page 104.

[48] The Humane Society of the United States. June 2021. *A call to end wolf trophy hunting in Wisconsin.* https://www.humanesociety.org/sites/default/files/docs/HSUS-WI-Wolf-Report15Jun2021.pdf; Treves, A., & Louchouarn, N. X. (2022). Uncertainty and precaution in hunting wolves twice in a year. *Plos one, 17*(3), e0259604; Wisconsin's Green Fire. (2021).

With that said, we are concerned by the DNR's use of a scaled occupancy model to estimate wolf abundance.[49] Treves & Santiago-Avila (2023 preprint) detailed major shortcomings in the DNR's use of a scaled occupancy model and conclude that, "[T]he Wisconsin method would systematically overestimate wolf abundance by large (but currently incalculable) margins."[50] Using this flawed method as the basis for the wolf population estimate and therefore for future quota setting could irreparably harm Wisconsin's wolf population.

We are also deeply concerned that two of the three strategies under Objective C: Provide Multiple Benefits Associated with the Wolf Population are focused on wolf trophy hunting and trapping. Just 11% of Wisconsinites hold hunting licenses, and an even smaller percentage are interested in trophy hunting and trapping wolves. This Objective should instead focus on the many benefits wolves provide to *all* Wisconsinites, including those related to biodiversity and the ecosystem, disease reduction, and preventing deer-vehicle collisions, as will be discussed in Section 5 of these comments. Strategy C3 is a start but could be greatly expanded.

Furthermore, we are vehemently opposed to Product C2h, which recommends "pursing administrative rules to establish a designated season for dog owners to train for wolf hunting activities."[51] We do not support any pursuit of wolves with hounds. Using dogs to chase wolves, whether for hound training or as part of wolf trophy hunting, amounts to state sanctioned dog fighting and puts both wolves and dogs in jeopardy. Allowing a hound training season will undoubtedly increase conflict, create social chaos among wolves, and lead to increased harassment of nontarget wildlife and trespass issues with landowners.[52]

Strategies C1 and C2 also ignore the fact that wolves have intrinsic value. —that is they have value in their own right beyond their use to humans and the benefits they provide to the ecosystem and the eco-tourism economy.[53] Wolves are incredibly intelligent, social, and family-oriented animals[54] and Wisconsin has a responsibility to ethically conserve their population. As such, the final plan should include a recommendation that wolf quotas be set to zero and/or that state statute be changed to not require Wisconsin hold a wolf trophy hunting and trapping season when wolves are not federally protected.

3. Conflicts with wolves are rare in Wisconsin and non-lethal tools are the most effective means for conflict prevention

Livestock losses to wolves are extremely rare in Wisconsin and in every jurisdiction in which they live.[55] The draft plan even acknowledges that, "the total number of farms and livestock involved in wolf

The February 2021 Wisconsin wolf hunt: A preliminary assessment. https://wigreenfire.org/2019/wp-content/uploads/2021/04/WGF-Cons-Bulletin-Feb-Wolf-Hunt-04-28-2021.pdf.

depredation and harassment incidents across Wisconsin are numerically low."[56] According to information provided in Section 3 of the draft plan, "The number of farms with verified wolf depredations has averaged about 30 farms from 2011-2021."[57] Furthermore, the most recent Wisconsin Gray Wolf Monitoring Report states that between April 15, 2021 and April 14, 2022, 46 cattle, 17 sheep, and 3 horses were confirmed to have been killed or injured by wolves.[58] To put that into perspective, at the time there were approximately 3.5 million cattle and 86,000 sheep in Wisconsin.[59] In other words, wolves were confirmed to be responsible for the death or injury less than 0.002% of the cattle and sheep in Wisconsin.

Not only are livestock losses to wolves rare and far less lethal than health, weather, and birthing problems,[60] but many studies have questioned the efficacy of killing wolves to reduce or prevent livestock losses.[61] For example, Treves et al. (2022, *preprint*) state:

> Therefore, the majority of studies suggest wolf-killing as practiced in the USA, France, and Slovenia does not prevent future livestock losses reliably and can, in fact, sometimes raise such losses. Therefore, the most rigorous and replicable research to date found that targeted wolf-killing appeared effective for preventing recurrent livestock killing in only a minority of cases. Furthermore, the risk of raising livestock losses appears in numerous studies cited in those summarized above.[62]

In other words, studies have found that killing wolves does not improve livestock safety and can actually exacerbate conflicts with livestock by disrupting the stable social structures that wolves rely on.[63] For example, when wildlife biologists reviewed a 17-year data set involving Michigan wolves and livestock losses, they discovered that the lethal removal of wolves for livestock protection reasons on one farm

increased future wolf predation on their neighbors' livestock.[64] Several other studies show that killing wolves, including by predator control, does little to protect livestock.[65] Even the literature review included in Section 2 of the draft plan details studies demonstrating that killing wolves is consistently found to be less effective at stopping livestock-wolf conflicts when compared to non-lethal preventative measures, concluding, "Tolerance for wolves may increase as research on non-lethal wolf control methods continues to improve, and if agencies pair communications on reducing risks with information about the benefits of maintaining wolves on the landscape."[66]

Non-lethal methods to protect livestock are more effective, economical, and humane than killing wolves.[67] For example, in their study evaluating low-stress livestock handling (referred to by the authors as "L-SLH"), Louchouarn and Treves (2023) report that:

> Our experiment shows that one can graze thousands of cattle safely on vast public lands hosting grizzly bears and wolves when owners use L-SLH as a method to reduce the vulnerability of domestic animals. We conclude that L-SLH joins a growing number of non-lethal, carnivore control methods proven effective by gold standard experiments.[68]

Other benefits conferred from low-stress livestock handling and range riding include quickly finding and removing cattle who die from maladies, birthing problems or lightning strikes that could attract predators, as well as observing and managing other problems affecting the herd in a timely manner.[69]

Again, killing wolves can actually exacerbate conflicts with livestock by disrupting the stable social structures that wolves rely on. For example, Bryan et al. (2015) write: "Hunting can decrease pack size, which results in altered predation patterns, increased time spent defending kill sites from scavengers, and may lead to increased conflict with humans and livestock."[70]

A. Changes must be made to align the final plan with the best available science

We appreciate that the draft plan overall seems to favor non-lethal conflict prevention practices. Specifically, Product B1h, which aims to develop "Wolf Conflict Mitigation Plans that focus on non-lethal abatement" for farms with chronic livestock-wolf conflicts, is a step in the right direction to mitigating already rare conflicts with livestock in a way that supports public values and the best available science. We also support the strategies related to increasing public education related to the implementation of nonlethal conflict deterrent techniques, including those outlined under Strategies B5, B6, and E3.

However, the draft plan continues to exaggerate livestock-wolf conflict and provides little discussion of [redacted]ting that non-lethal conflict prevention measures are more effective at preventing conflicts than killing wolves. While the draft plan does provide some recommendations and

plans for outreach regarding non-lethal measures it should also include a more robust discussion of *why* such methods must be prioritized, particularly in Section 3 and Section 4, Objective B.

Killing wolves should never be the first response to livestock-wolf conflict, yet the draft plan indicates that this could occur.[71] Non-lethal methods that are properly implemented and appropriate for the situation should always be the primary response to conflicts. Furthermore, under Product B1f, the draft plan recommends that trophy hunting and trapping of wolves be used in an attempt address livestock-wolf conflicts. Similarly, the draft plan recommends delineating Subzones 1A and 4A to allow the Commission and the DNR to provide increased trophy hunting and trapping opportunities in areas that have historically experienced chronic conflict.[72] As thoroughly discussed above, there is little evidence that killing wolves, especially through trophy hunting and trapping seasons, will resolve conflicts.[73] In fact, trophy hunting and trapping can make conflicts worse.[74] As such, Product B1f and the delineation of Subzones 1A and 4A should be removed from the final plan.

In an effort to increase transparency, information about investigations into suspected livestock-wolf conflict, including what, if any, non-lethal deterrents were in place at the time, should be made readily available on the DNR's website, with any identifying information redacted. Additionally, the DNR should require that livestock producers properly implement adequate non-lethal tools to prevent conflicts prior to providing any compensation for losses.

4. Killing wolves will not increase already high ungulate populations; wolves suppress and limit diseases, including CWD

Recent research suggests that while native carnivores like wolves can accelerate declines in prey populations and modulate increases, predation alone does not cause these changes in populations.[75] Weather, disease, and habitat play a much greater role in determining deer and other ungulate population sizes.[76] Killing native carnivores like wolves fails to address the underlying environmental issues—such as habitat loss, drought, loss of migration corridors, human growth, oil and gas exploration and inadequate nutrition—that harm prey populations such as deer.[77]

Further, a meta-analysis of predator-prey studies assessing the overall effect of predator removal on wild ungulate populations found that predator removal had low and variable effectiveness on increasing ungulate populations.[78] Another recent study analyzing four decades of efforts in Alaska to reduce abundance of large

predators, including gray wolves, brown bears and black bears, found that there was no difference in average moose hunting success during periods of recent liberalized killing of predators relative to prior periods.[79]

The scientific consensus for the last several decades has generally found that coursing predators like wolves and coyotes balance prey populations and make them more robust,[80] including removing the sick and weak animals who would die of other natural causes anyway.[81] Predator-control schemes, including recreational hunting and trapping, are an unreliable way to increase the abundance of deer and other ungulates.[82]

Wolves are very good at identifying vulnerable prey, and tend to target individuals that are old, young, sick, or otherwise weakened.[83] The draft plan even mentions that wolves are highly effective at identifying prey weaknesses.[84] They prefer to prey upon deer who are already in poor health or otherwise compromised. We appreciate that the draft plan includes a robust discussion of the role wolves and other native carnivores play in suppressing and limiting the prevalence of disease in prey species, including chronic wasting disease (CWD),[85] an epidemic plaguing cervids that continues to spread across North America, including in Wisconsin.[86] Wolf predation can limit or even prevent transmission of CWD and other diseases by reducing host densities and contact rates or by lowering the total number of infected individuals in a host population.[87]

Moreover, Wisconsin's deer population is doing well. On its website, the DNR states:

[87] Wild et al., 2011.

> Recognized nationwide as one of the country's premier white-tailed deer hunting states, Wisconsin has both an abundant herd and a proven reputation for producing some of the largest bucks in the world.[88]

Furthermore, based on preliminary figures released on November 29, 2022, the total number of deer hunted with firearms increased 14.4% statewide compared to 2021.[89] That news release also stated that the number of deer hunted with firearms increased in all four deer management zones, including the Central Forest Zone (+30.6%) and the Northern Forest Zone (+19.3%). Wisconsin's deer need wolves to keep them healthy. Unlike humans, who prey on prime age breeding animals, wolves take the sick and the weak leaving the herd stronger.[90]

A. Changes must be made to align the final plan with the best available science

While we appreciate the discussions in the draft plan about predatory-prey dynamics and selective predation and CWD,[91] we do have a few remaining concerns regarding the draft plan's strategies regarding wolves and prey that must be addressed. Specifically, Strategy A5 states that, "Public concerns regarding the impacts of wolves on white-tailed deer populations (whether real and perceived) will continue to require attention to maintain and/or improve public support for wolves."[92] This language implies that perceived harms from wolves—even ones that do not hold up under scientific scrutiny—could be used as justification for reducing wolf numbers by killing them. This is wholly unacceptable and must be removed from the final plan.

Product A5c also implies that even though the elk population has continued to grow in areas with wolves and that, "As elk numbers increase, the impacts of wolves as a limiting factor on elk population growth is likely to diminish with each year of elk population increase,"[93] wolves could be more heavily persecuted in elk zones.

To be clear, Wisconsin's wolves should never be killed with the hopes of growing ungulate populations for hunters. Doing so is not backed by sound science and it will fail, nor is it socially acceptable. Wolves should not be persecuted for suspicion or for performing their ecological function. Instead, the DNR should focus on educating the public about the benefits wolves provide and an accurate portrayal of wolf-prey dynamics.

5. Wolves are valuable and provide many ecological and economic benefits

In addition to their ability to mitigate the spread of CWD and other diseases (described above), wolves significantly and positively influence biological diversity and ecosystem function.[94] By curbing deer over-

browsing, wolves can reinvigorate the understory of plant communities, increasing flora and fauna biological diversity including bird life.[95] Wolf presence in the Great Lakes region affects soil nutrients, soil microbes, and plant quality because decomposing prey carcasses enrich soils.[96] Elevated Great Lakes deer populations not only destroy forest ecosystems, but are also involved in numerous vehicle collisions and carry Lyme, a zoonotic disease.[97] Recent studies demonstrate that wolves can reduce deer-vehicle collisions saving millions in social costs.[98] Similarly, ecologically functioning populations of wolves have been instrumental in restoring biological diversity in the Northern Rocky Mountains, including increasing the number of songbirds, pronghorn, lynx, and other species, while simultaneously improving the ecology of vital riparian systems.[99]

While we appreciate the discussion regarding trophic cascades included in the draft plan, we are concerned by language that seems to dismiss these effects as exaggerated or "romanticized."[100] Additionally, rather than focusing on trophy hunting and trapping under Objective C: Provide Multiple Benefits Associated with the Wolf Population, the final plan should include strategies to facilitate the positive effects wolves have on our ecosystem, and public education strategies under Objective D should include plans to educate the public about the many benefits wolves provide. We support the DNR's aim to "Support research into the role wolves may play in relevant ecological processes such as forest regeneration and disease transmission," as outlined under Product E5a.[101] The DNR should also make a point to share the results of that research with the public as it becomes available.

Finally, as discussed in Section 2 of these comments, wolves have intrinsic value.[102] Wolves have rich social and family lives, experience pleasure and pain, are sentient, and deserve to be treated as ethically

important in their own right.[103] More generally, to best reflect Wisconsin values, ethical discussions should be incorporated throughout the final plan. Product C3b is a good start and should be expanded and better incorporated throughout the final plan.

6. Conclusion

The draft plan includes many important changes and is a significant improvement over the previous Wolf Management Plan. We sincerely appreciate the DNR's efforts to update the biological and social science that will inform wolf management. We are also deeply grateful for having been included in the Wolf Management Plan Committee.

Our biggest concern with the current draft plan is the overall focus on wolf trophy hunting and trapping. While we understand that Wisconsin law mandates such seasons when wolves are not federally protected under the Endangered Species Act, the plan should include more discussion of the immense harms trophy hunting and trapping cause to wolves and recommend policy changes to mitigate these effects. The final plan could recommend quotas be set at zero or that state statute be changed to remove the requirement that Wisconsin hold wolf seasons.

We also recommend that the final plan more clearly prioritize nonlethal conflict prevention measures and include more information about the scientific studies demonstrating that non-lethal conflict prevention measures are much more effective at preventing conflicts than killing wolves. Killing wolves should never be the first response to conflicts and the use of properly implemented, appropriate non-lethal deterrents should be required in order for compensation to occur.

Finally, as demonstrated by the 2022 public attitudes survey detailed in the draft plan and other surveys and polls, the majority of Wisconsinites clearly value wolves and want them to thrive in Wisconsin. The final plan should commit to giving *all* Wisconsinites a seat at the table in guiding future wolf policy and these values should be more proportionately represented in groups that have influence over wolf policy.

Thank you for this opportunity to provide input on the draft plan.

Sincerely,

Megan Nicholson
State Director, Wisconsin

Re: Wisconsin 2022 Draft Wolf Management Plan
Via: *DNRWildlifeSwitchboard@wisconsin.gov*

Esteemed WDNR staff,

On behalf of Project Coyote, The Rewilding Institute and our Wisconsin supporters, we submit the following public comments on the 2022 Wisconsin Draft Wolf Management Plan. Our comments express grave concerns over: (1) the substantial amount of high-quality scientific literature that is arbitrarily omitted from the plan, (2) the arbitrary and contradictory prioritization of consumptive uses and, along with it, (3) unscientific biases promoting the instrumentalization of wolves for any human benefit, despite public values that strive for increased consideration of wolves and peaceful coexistence.

We expand on each point of concern in our detailed comments below and include a list of crucial academic literature. We encourage the department to not only consider but integrate the below comments, scientific literature and their ecological, social, ethical and policy implications if the objective is to truly strive for a plan that is guided by public values that strive for coexistence and informed by the best-available science.

Sincerely,

Francisco J. Santiago-Ávila, PhD
Science and Conservation Manager
Project Coyote & The Rewilding Institute

Michelle L. Lute, PhD
Carnivore Conservation Director
Project Coyote

General comments

We appreciate the efforts of all WDNR staff involved in updating the state's wolf management plan. Although we believe the current plan needs significant updating (see next section), we recognize the efforts and improvements made to the previous plan, including:

- Wolves in WI will no longer be managed by reference to the old numerical goal of 350 wolves.
- There is much greater recognition of the ecological role of wolves.
- The inclusion of a social survey, which notes increased positive views of wolves, knowledge of their ecological roles and increased opposition to the motives and methods for killing wolves.
- The adoption of proposed buffer zones around tribal reservations (i.e., previously no buffer zones existed).

However, as explained in our detailed comments below, the current draft does not reflect the best available science, and is missing a substantial amount of scientific literature on (see reference list below):

- wolf ethology, sentience, sapience, sociability, agency and wellbeing
- effectiveness of non-lethal interventions, especially relative to lethal ones
- the impact of widespread killing on wolves' physiology, behavior, wellbeing, social dynamics, ecological relationships and evolution.

The above scientific omissions, combined with the emphasis on and promotion of 'sustainable' recreational killing and consumptive users as a main management strategy, results in a biased plan that runs contrary to scientific evidence despite much of this omitted science being more recent, numerous and of stronger inference.

Instead, **the plan should strictly curtail any lethal management of wolves except in extremely rare circumstances of immediate defense of life**. A substantial body of research documenting human-caused mortality in North American wolves, including Wisconsin wolves, has found that policies allowing liberalized killing of wolves result in a direct increase in the hazard and incidence of illegal killings. Moreover, hounding or hound training, which are akin to allowing legalized dogfighting, should be illegal or severely restricted as this practice is extremely cruel to wolves and hounds alike and is not supported by the majority of hunters or the broad public.

The plan should prioritize wolf protections and concentrate solely on non-lethal management of wolves in response to conflict with domesticated animals to ensure ethical coexistence. We remind the WDNR that despite Act 169, which mandates a wolf hunting season, the department can still restrict the implementation of lethal methods by setting minimal quotas, including a quota of '0' wolves, and restricting timing and methods. Such measures are consistent with the scientific literature, as several studies have proven a proactive non-lethal approach leads to better conflict mitigation. There is plenty of evidence suggesting lethal management often fails to provide a long-term solution to wolf predation and has the least consistent success rates when compared to non-lethal practices. In addition, there is significant evidence showing that lethal wolf management may be less functionally effective at mitigating subsequent livestock losses than non-lethal deterrents. Given such substantial evidence, the plan

should *require* the implementation of abatement measures as well as the use of non-lethal conflict minimization techniques by domestic animal guardians for the latter to receive compensation for confirmed predation.

The plan also runs contrary to public values towards wolves (and omits mention of such majority values from the plan), despite department surveys evidencing that the broad public cares about wolves as individuals (and not just for the viability of the population). Especially given the recent liberalization of killing wolves by the state, it would be incredibly informative to note majority support of the following reasons for opposing a regulated wolf hunting/trapping season (which are all omitted from the plan): opposition to specific methods of harvest like hounds (64%) or traps (70%), feelings that hunting wolves is unnecessary (62%) or culturally offensive to Native American tribes (57%). All such reasons convey majority disagreement with practices currently promoted and endorsed by the legislature and the WDNR, and such a conflict between managers and the public should not only be acknowledged, but foregrounded and carefully considered in policy (instead of dismissed). Such decisions to omit literature or downplay evidence (e.g., such as majority opposition to killing wolves and their reasons) are contrary to principles of scientific integrity (e.g., present all relevant scientific evidence to the public) as well as ethics (e.g., disguising ethical decisions, such as recreational wolf killing, as robustly supported by science). More pragmatically, ignoring evidence and public values leads to inconsistent and litigious plans and policy, leading to ineffective, expensive and contentious public policy.

It is also incredibly concerning that **conflicting agency objectives (e.g., optimizing public hunting and conflict mitigation) are not only not acknowledged, but even misunderstood as harmonious, against the body of scientific evidence**. That culminates in the prioritization of consumptive values and policies; e.g., according to the body of scientific literature, use of lethal methods, and especially public hunts, are contrary to most objectives relevant to: harm mitigation, the wellbeing of wolves, their ecological roles, and wolves' non-exploitative enjoyment by humans (i.e., Objectives A, B, D and F).

Additionally, **the plan is clearly biased against the interests of wolves and their advocates, despite broad public, tribal and scientific support**. There is a stark lack of consideration for individual wolves, wolf population health (including wellbeing), and measurable indicators for assessing any harms barring disease prevalence (e.g., accounting for cortisol levels or other stress hormones, measures of pair/pack persistence).

Similarly, **there is an inappropriate understanding and consideration of tribal worldviews about wolves**. Tribal worldviews of wolves are misconstrued as 'cultural benefits' tribes receive from the existence of a wolf population, when in fact tribal worldviews consider *each individual wolf* as a *person* and *relative*. Cultural respect and sensitivity towards such views, shared by many non-tribal members, demand the strict mitigation of lethal measures, especially recreational killing, as opposed to their current promotion in the plan.

Lastly, **we point to a recent critique of the state's new 'SOM' wolf estimation methodology to highlight the substantial scientific concerns over its adequacy and reliability**: "The new methods sacrifice precision, but are believed to retain adequate accuracy and sensitivity to

changing conditions for reliable decision-making. We review evidence for the accuracy, precision, and sensitivity of the new 'scaled occupancy model' (SOM) applied in Wisconsin. We conclude that the Wisconsin method would systematically overestimate wolf abundance by large (but currently incalculable) margins. Because Wisconsin, similar to other states, not only changed to unverified methods but also implemented widespread wolf killing, shortcomings in their estimates of wolf abundance may have far-reaching consequences for population viability and confidence in state wildlife managers. We discuss findings from Wisconsin alongside similar findings for other states' occupancy models being insensitive to human causes of mortality that have recently increased. Overall, Wisconsin's proposed method for estimating wolf abundance shows significant departures from best practices in scientific measurement. Verification will require independent replication and unbiased tests at multiple scales in multiple habitats under different human-induced mortality rates, and peer review before the new methods are considered reliable." (Treves & Santiago-Ávila, 2023)

In general, all omissions of scientific literature, the arbitrary prioritization of policy objectives, the rhetoric of the plan and the dismissal of public values and concerns *for wolves* point towards a biased, unscientific and instrumental view of wolves that promotes values contrary to broad public perspectives on wolves. We expand on each of these points and many more in our detailed comments below.

Detailed comments

Section 1: Gray wolf biology, ecology and population dynamics

Such a review of gray wolf literature is not scientifically comprehensive. A comprehensive and holistic understanding of wolves, rather than a purely instrumental one, should include scientific information relevant to wolf sentience, consciousness/awareness, internal capabilities (cognition), social dynamics, and culture, of which there is substantial literature (see references below). Otherwise, the suggestion is that these animals are merely biological machines, which is an unscientific in addition to prejudiced view of wolves.

Social system

This information, and especially that specific to pack structure, should be updated to convey a more appropriate understanding of the pack as a family instead of a 'dominance hierarchy', which reflects a misunderstanding about wolf families in the wild which are mostly composed of parents and their offspring (according to the departments own research), hence the 'leading' of the breeding pair (based on natural deference/submissiveness to parents).

Communication

This section is missing holistic understanding and exposition. Wolves are sentient, self-aware beings (Birch et al. 2020, Low et al. 2012, Safina 2015). Wolves communicate *due to* their high sentience, consciousness and cognition, and a holistic exposition of wolf science should include the latest science on this understanding. As an example, consider Mazzini et al's (2013) study on how *relationship quality* mediates wolf howling:

> *While considerable research has addressed the function of animal vocalizations, the proximate mechanisms driving call production remain surprisingly unclear. Vocalizations may be* ***driven by emotions*** *and the physiological state evoked by changes in the social-ecological environment [1, 2], or animals may have more control over their*

> *vocalizations, using them in flexible ways mediated* ***by the animal's understanding of its surrounding social world*** *[3, 4]. While both explanations are plausible and neither excludes the other, to date no study has attempted to experimentally investigate* ***the influence of both emotional and cognitive factors*** *on animal vocal usage. We aimed to disentangle the relative contribution of both mechanisms by examining howling in captive wolves. Using a separation experiment and by measuring cortisol levels, we specifically investigated whether howling is a physiological stress response to group fragmentation [5] and whether it is driven by social factors, particularly relationship quality [6, 7].* ***Results showed that relationship quality between the howler and the leaving individual better predicted howling than did the current physiological state.*** *Our findings shed important light on the degree to which animal vocal production can be considered as voluntary.*

See also Palacios et al. 2015 & Kershenbaum et al. 2016 on how canid communication is mediated by emotional, cognitive and social processes integral to population dynamics in a cooperative species.

Mortality

"Gray wolves have high reproductive potential and populations in general are resilient in the face of severe disruptions or population declines, with the ability to rebound quickly if the disruption is reduced after an event (USFWS 2012, 2020, Fuller 2003, Hayes and Harestad 2000b)." (p. 12-13) This is the first of multiple instances of a statement that conveys an instrumental understanding of wolves and suggests that wolves can sustain substantial human-caused mortality. Repeated in the document (see other instances below), and in a context where evidence of the internal, emotional, cognitive and social capabilities and dynamics of wolves are omitted, such statement(s) promote a particular ethical view of wolves as expendable, and are insensitive to those who consider wolves beings worthy of care and respect by dismissing such ethically relevant qualities.

Selective Predation and Chronic Wasting Disease

This section is missing the following important literature relevant to positive effects of wolves in mitigating disease transmission in prey species: Tanner et al. (2019) and Hoy et al. (2022). Both studies provide evidence for wolves providing unaccounted for ecosystem services in the form of reduced levels of indirect transmission of diseases (e.g., tuberculosis in wild boar, Tanner et al. 2019) and as a selective pressure (through predation) against genes associated with developing diseases (e.g., severe osteoarthritis in Hoy et al. 2022). Importantly, both studies point to increased benefits of allowing predators to naturally regulate their prey populations, with beneficial effects on prey populations. As stated by Hoy et al (2022): "The evidence we present for predation's influence on the health of prey populations is also relevant for policy-related arguments about refraining from intensively hunting wolf populations." given their results were obtained from a system unaffected by anthropogenic wolf mortality (Isle Royale National Park). Such studies suggest hunting would mitigate such benefits, but the current plan does not explicitly acknowledge the tradeoff of such broad ecosystem benefits for the sake of providing a minority of individuals the opportunity to kill hundreds of wolves annually through public hunts.

Predator-Prey Dynamics

This section is missing the substantial and recent scientific literature relevant to concerns over reduced wild ungulate populations, suggesting that killing wolves may not be favorable to hunting of wild ungulates. A recent meta-analysis of predator-prey studies exploring the overall effect of predator removal on ungulate populations found predator removal had low and variable effectiveness for increasing wild ungulate populations (Clark and Hebblewhite 2021). In Alberta, a recent study shows that "increasing large-predator populations do not necessarily reduce hunter harvest of elk" and that sustainable hunting of elk has continued, and populations have increased with increasing large predator populations (Trump et al. 2022). In Alaska, a recent study analyzing 4 decades of efforts to reduce abundance of large predators, including gray wolves and brown/black bears found: (1) no positive correlations between harvests of bears and subsequent moose harvests, (2) moose harvest was negatively correlated with the prior year's wolf harvests (weak relationship) and (3) no differences in mean moose harvests during periods of recent liberalized killing relative to prior periods (Miller et al. 2022). Such evidence at the population level is consistent with prior and recent research documenting how wolves have primarily compensatory and weak additive effects on population dynamics (Vucetich et al. 2005, Christianson & Creel 2014, Griffin et al. 2011, Brodie et al. 2013) of wild ungulates, given their focus on calves and older females with low reproductive value (Eberhardt et al. 2007; see also Wilmers et al. 2020).

Gray Wolf Population Dynamics

"Due to an adaptable and redundant life-history strategy, research across the world and spanning decades has consistently shown wolf populations to be resilient and persistent, so long as these two factors [prey availability and cumulative mortality] remain adequate." (p.18) This is the second instance of a statement that conveys an instrumental understanding of wolves and suggests that wolves can sustain substantial human-caused mortality. Repeated in the document (see other instances below), and in a context where evidence of the internal, emotional, cognitive and social capabilities and dynamics of wolves are omitted, such statements promote a particular ethical view of wolves as expendable and are insensitive to those who consider wolves beings worthy of care and respect by dismissing such ethically relevant qualities.

Additionally, considering the whole scientific literature, the statement above is also inaccurate because it fails to distinguish the effects of distinct causes of mortality, such as human-caused mortality, on the resiliency and persistence of *healthy* wolf populations. As an analogy, we could also say that human populations are incredibly resilient and persistent if there is food and low mortality, but this would not be very informative for the *state of health* of the human population or the wellbeing of individual humans.

Impacts of Regulated Harvest on Wolf Dynamics

We find this section omits important work on the biological, ecological, evolutionary and ethical implications of killing wolves, in particular how killing negatively impacts wolves' physiology and behavior (Almberg et al. 2015, Bryan et al. 2015, Pereira et al. 2022;) which build up to negative impacts on wolf dynamics (Adams et al. 2008, Ausband et al. 2015, Ausband et al. 2017, Brainerd et al. 2008, Borg et al. 2015, Cassidy et al. 2023, Creel & Rotella 2010, Creel et al. 2015, Fuller et al. 2003, Haber 1996, Milleret et al. 2017, Mitchell et al. 2008, Murray et al.

2010, Rich et al. 2012, Rutledge et al. 2010, Sparkman et al. 2011, Vucetich 2012) including wellbeing, fitness, ecological relationships (e.g., "human actions will often attenuate the ecological effects of large carnivores", Kuijper et al. 2016; see also Ordiz et al. 2013) and evolution (Wallach et al. 2009, Wallach et al. 2015). As many such studies have noted (see Wallach et al. 2009 and Ordiz et al. 2013), killing large carnivores reduces the quality of traits that define them as apex predators. In the case of wolves, the cooperative behaviors that underlie their ecology and dynamics are hindered through the social break-up of the family group, and such social instability highly constrains their ecological effects because "the pack is the apex predator, not the single individuals" (Wallach et al. 2009). We note that none of this literature relevant to harms to wolves as individuals, social units and population(s) is included in the plan, with the outcome that such trade-offs seem non-existent or inconsequential for wolf policy. Such omissions provide further evidence of bias within the plan and department in favor of the use of lethal methods and the instrumentalization of wolves, as the resulting harms are neither acknowledged nor highlighted as concerns for future research.

Moreover, the plan states that "These findings highlight the importance of considering factors outside of abundance that contribute to wolves' long-term fitness and persistence of populations (Rutledge et al. 2010)." (p.21) However, except for abundance, no other factors inherent to wolves' wellbeing, physiology (barring disease) or social dynamics (see list above and reference list) seem to be adequately considered anywhere in the plan, and especially for allowing public hunts, despite the ample literature documenting negative ecological and evolutionary implications of exploitation. For example, Rutledge et al. (2010) (cited by the department in the quote above) point to the importance of maintaining stable social structures for long-term fitness, and lists evidence of its importance for various ecological processes such as resource use (Sand et al. 2006; Stahler et al. 2006) and pup survival (Brainerd et al., 2008; Schmidt et al., 2008). Yet, such evidence is dismissed when it comes to setting policy, including the sanctioning and promotion of liberalized killing.

The concerns over the omitted literature and its resulting bias are exacerbated by yet another statement seeking to inspire confidence on the *alleged, not evidenced,* reliability of wolf populations to exploitation: "Nevertheless, numerous wolf populations exposed to harvest and other sources of human-caused mortality have been studied over the last several decades and collectively have suggested that wolf populations are *remarkably resilient* to human-caused mortality, including regulated harvest." (p. 21) This is the third instance of such a statement (see above) attempting to normalize the killing of wolves for recreation and suggesting wolves can sustain substantial human-caused mortality seemingly without any consequences to be considered for wolf dynamics, ecology or evolution. Repeated in the document (see other instances below), and in a context where evidence of the internal, emotional, cognitive and social capabilities and dynamics of wolves are omitted, such statements promote a particular ethical view of wolves as expendable and are insensitive to those who consider wolves as beings worthy of care and respect. As stated previously, the bias towards lethal interventions and dismissal of wolves is made even starker when considering the amount of science relevant to negative impacts of killing on wolves that has been dismissed with the glib acknowledgment that other factors besides abundance should be considered.

Lastly, the reference list is missing the 'Bassing et al. 2019, 2020' studies cited in this section, which actually further add to the arguments above (see reference list).

Section 2: Human Dimensions and Cultural Significance

Although it is true that "...lethal control options (e.g., damage tags) may empower local residents and provide *a sense* of security." (p. 27), the scientific evidence against the functional effectiveness of lethal methods suggests it is a false sense of security given it notes the ineffectiveness and counterproductive effects of lethal interventions for conflict mitigation (e.g., Bruns et al. 2020, Eklund et al. 2017, Khorozyan and Waltert 2019, Lennox et al. 2018, Miller al. 2016, Treves et al. 2016, van Eeden et al. 2018a,b; see Santiago-Ávila et al. 2018a,b for a comparative study from the Great Lakes region). According to the scientific literature on the (in)effectiveness of lethal methods, such a 'false' empowerment and sense of security comes at the cost of not only actually preventing, but also exacerbating conflicts; i.e., the cost of this sense of empowerment is the *actual* security of individuals and domesticated animals (e.g., Haber 1996, Santiago-Ávila et al. 2018a,b, Treves et al. 2016,van Eeden et al. 2018b). Moreover, research from the Great Lakes has also documented the effectiveness of non-lethal methods in conflict prevention and mitigation (Davidson-Nelson & Gehring 2010, Gehring et al. 2010). This scientific evidence has yet to be added to the plan, hence the tradeoffs are not acknowledged, the public is misinformed and policy is not only ineffective, but increases harms to wolves, domesticated animals and their guardians. The relevant scientific evidence easily fits into the discussion on page 28 as well as any sections on conflict mitigation.

This section also blatantly and cursorily misinterprets important peer-reviewed studies challenging the 'killing for tolerance' hypothesis, misinforming the public in the process. Referring to Chapron & Treves (2016) and Santiago-Ávila et al. (2020a), the plan states: "The disappearance of collared wolves from data may also be due to mechanical failure of the collar or from the wolf emigrating out of radio-telemetry range." (p. 27) As the lead author of one of those studies, I would like to note the biased nature of this statement, which glibly disputes and dismisses the lengthy discussion in the articles on this very point without mentioning the studies challenge such a cursory interpretation. Scientific integrity demands that the department omit such a statement or, alternatively, the inclusion of an explicit and lengthy engagement with the relevant arguments in Santiago-Ávila et al. (2020a).

"The top two priorities for lethal control of wolves among survey respondents were to respond to cases involving threats to public safety and to eliminate wolves from areas where they were attacking livestock." (p. 33) These priorities speak to a lack of public understanding on the lack of effectiveness and negative impacts of lethal methods on wolves, which exacerbate conflicts and increase risk of harm to domesticated animals and humans. This should be taken as an indicator that the agency should do a better job of educating on these issues, so as to increase proper understanding of wolf dynamics and reduce such harmful misperceptions.

"3. Most people would worry for the safety of their pets and children when recreating in areas where wolves live." (p.34-35) Likewise, this statement suggests the agency should increase the provision of appropriate information on the low level of conflicts related to humans and pets, and how to prevent them, given many conflicts are due to lack of education or lack of appropriate human behavior and precaution.

"...the top reason for opposition in 2022 was concern that wolves would become endangered again. The least selected reason for opposing a regulated wolf hunting and trapping season in

both 2014 and 2022 surveys was 'I oppose all forms of hunting'." (p. 36) What is included and excluded from this section speaks loudly. For example, even more striking than the quote above is that most of the public opposes wolf hunting for a variety of reasons. Given the recent liberalization of killing wolves by the state, it would be incredibly informative to note majority support for the following reasons for opposing a regulated wolf hunting/trapping season: opposition to specific methods of harvest like hounds (64%) or traps (70%), and feelings that hunting wolves is unnecessary (62%) or culturally offensive to Native American tribes (57%). All such reasons convey majority disagreement with practices currently sanctioned and promoted by the legislature and the WDNR, and such a conflict between managers and the public should be not only acknowledged, but foregrounded and carefully considered in policy. At the very least, such objections of the broad public should be noted somewhere in the plan, yet are not, arguably given the stated opposition to agency policies.

Part Three: Wisconsin Tribal Perspectives and Cultural Significance
We argue the plan enshrines and promotes the instrumentalization of wolves as opposed to their inherent value, lives and wellbeing, given the plan's focus on benefits for humans, especially consumptive benefits (e.g., killing wolves). Despite the agency invitation to First Nations to state their cultural worldviews and values, the inherent value of wolves championed by some tribes, most notably the Ojibwe, is unreflectively misinterpreted as a social/cultural 'benefit' wolves provide tribal members, which is completely contrary to the definition of inherent value as individual beings valuable for themselves, rather than what they can provide to humans. Wolves have intrinsic value for tribal members and many other humans because *each wolf* is considered a person or relative (David 2009). This is not a 'social/cultural benefit' of their existence (i.e., 'existence value'), but rather a worldview that extends respect and protection to all *individual* wolves, not just the population. The denial and misinterpretation of intrinsic value is insensitive and disrespectful to tribes and all others who consider wolves relatives and persons. Those individuals are harmed each time an individual wolf is killed, rather than consider the 'benefit' of a wolf population. In addition, such misinterpretation does a disservice to respectful intercultural dialogue and understanding. The state should also note that the view of wolves and the wolf policies advocated by the Ojibwe (e.g., self-regulation of wolf populations for ecological purposes, no lethal management) are far more holistic and aligned with current scientific understanding than those promoted by the state (Gilbert et al. 2022).

<u>Section 3: Gray Wolves in Wisconsin</u>
Population Mortality Patterns (in *Historical Overview of Wolves in Wisconsin*)
This section is missing two notable references analyzing wolf mortality patterns in Wisconsin, as they relate to lethal management methods, seasonality and other environmental and policy factors: Santiago-Ávila et al 2020a, 2022b). Other relevant studies from other wolf populations include Louchouarn et al. 2021 and Santiago-Ávila et al. 2022a.

Wolf Harvest Management
Quota Setting Process — Despite mention of the "numerous factors" the department allegedly considers when developing quotas, there is only explicit mention and discussion of quota effects on wolf population *size*. There is absolutely no discussion of how the following factors are considered into the quota process: projected impacts of wolf harvest quotas on wolf physiology, dynamics, social structure, wellbeing, conflicts, disease, illegal killing, ecological relationships

or evolution (see comments on ‘Impact of Regulated Harvest on Wolf Dynamics’, Section 1, and reference list, e.g.,: Haber et al. 1995, Almberg et al. 2015, Bryan et al. 2015, Wallach et al. 2015, Kuijper et al. 2016, Santiago-Ávila et al. 2018, Pereira et al. 2022).

“Upon determination of a suitable quota, the total quota is allocated among the six wolf harvest zones (Figure 20). The application of harvest pressure geographically may further be informed by different philosophical and management objectives.” (p. 68) Other than vaguely describing factors to consider, the plan does not explain the process for “determination of a suitable quota”, despite acknowledging that substantial agreement on this and other matters has proven elusive. Given this substantial disagreement in perspectives about wolf killing, any process and criteria for determining a quota should be explicitly described, to ensure equitable consideration of wolves, nature and the broad public. This description should explicitly include which matters, objectives or criteria were prioritized in such a process. For example, what priority is given to hunter/trapper opportunity and allowed methods relative to conflict mitigation and ecological benefits, and how is that represented in the current plan. This is particularly important given the broad majority of the public feels that killing wolves is unnecessary and culturally offensive, and does not agree with many methods (see comments on omitted information in Section 2).

Wolf Harvesting License Issuance – Please explain the process, criteria and discretion relevant to establishing a specific hunter/trapper success rate for issuing licenses. This is a critical part of the process and it seems to have fluctuated enormously in a discretionary and obscure fashion (10:1 to 20:1 ratio).

Wolf Harvest Registration and Hunter/Trapper Surveys – Please consider limiting registration time to 6-12 hours, given it can be done via website or phone and season closures depend on accurate, timely registration and updating of season quotas.

“The department has also surveyed successful license applicants following the completion of each wolf season to collect more data on hunter/trapper activities. This data provides more information on hunter effort and success, use and timing of various legal methods, hunter/trapper experiences and preferences, and applicant motivations. These surveys provide data to paint a fuller picture of the social parameters surrounding the wolf harvest season.” (p. 71) The social parameters surrounding the season are not limited to those who want to kill wolves. This type of overemphasis on hunters/trappers biases the department’s perspective towards promoting killing. To correct this bias, the department should also develop and promote an informed questionnaire for the non-consumptive public to gather more information on their perceptions of use/timing of various methods and motivations used for killing wolves. That will certainly provide a broader, clearer social context surrounding the season. That certainly forms the broader social parameter under which the wolf harvest season is held, and can initially be informed by the omitted statements for why the majority of individuals do not support wolf killing (see comments on Section 2).

As for licenses, it should be noted in the plan that State Licenses Purchased were always much lower than those awarded, and purchased licenses have always totaled <1,600. This provides a glimpse into the narrow group of individuals actually invested in hunting and trapping of wolves, as opposed to, for example, the majority of individuals that disagree with hunting them (62% of

8,750 = 5,452 only within the survey sample, a blatant underestimate) and with the methods used for doing so (70%, 6,125; see survey section above). Hence, the interests of hunters/trappers seem to be disproportionately prioritized relative to those of others, including not only wolf advocates and tribes, but also ranchers that are actually interested in science-based conflict reduction (which hunting/trapping may exacerbate).

Wolf-related conflict
"...the costs to individual livestock producers can be high, particularly in areas of chronic depredation activity." – The department should have data on the costs to individual livestock producers given their compensation program. This data should be provided to the public like any other data in this section, to evidence such a statement. How many farms experience chronic depredations, and what's the economic cost?

Non-depredation Impacts on Livestock – Although the thoroughness of this section is commendable, it provides a blatant contrast to the magnitude of missing scientific literature on wolf ethology, including sentient and cognitive capabilities, and the impacts of lethal methods on wolves, their physiology, psychology and social dynamics, despite the plan being about wolves (not 'livestock') and such science being of comparable or more important to the majority of the public who is not a domestic animal guardian and is favorable to wolf protections.

Abatement options – Alteration of animal husbandry practices (if more adequate ones exist) should be required prior to implementation of any other non-lethal methods given their potential to mitigate conflicts effectively, feasibly and economically, and especially given non-lethal methods may require particular changes in husbandry to be effective. Additionally, non-lethal methods should be required and exhausted prior to the consideration of lethal methods to mitigate the risk of subsequent conflicts. Non-lethal methods have been proven more effective, while lethal methods have been characterized as ineffectiveness and counterproductive for conflict mitigation (e.g., Bruns et al. 2020, Eklund et al. 2017, Khorozyan and Waltert 2019, Miller al. 2016, Lennox et al. 2018, Treves et al. 2016, van Eeden et al. 2018a,b; see Davidson-Nelson & Gehring 2010, Gehring et al. 2010 and Santiago-Ávila et al. 2018a,b for the Great Lakes region). This scientific evidence has yet to be added to the plan, hence the tradeoffs are not acknowledged, the public is misinformed and policy is not only ineffective, but increases harms to wolves, domesticated animals and their guardians. The relevant scientific evidence easily fits into the discussion on page 28 as well as any sections on conflict mitigation. In addition, this section should include an explanation of the decision-making process, criteria and discretion involved in determining when to implement lethal methods in response to verified conflicts.

"However, rendering facilities rarely service areas in northern Wisconsin where most depredations occur, and burial can be impractical and pose groundwater contamination and bio-security hazard risks. Composting is often recommended, but can be costly and requires proper site selection, a facility and equipment." (p.77) – That is beside the point if it is required, and it should also be a requirement prior to implementation of any interventions given it predisposes farms to predation.

Hunting Dog and Pet Conflicts – "Lethal controls may also be considered in response to verified pet conflicts" (p. 81) As with any other type of conflict, lethal interventions should be considered only after verification and exhaustion of non-lethal alternatives, including: responsible guardianship (not increasing chances of conflict, pets on leashes, pets indoors at night, not roaming, reducing attractants, etc.). Such measures should be required prior to any intervention, especially lethal(s). Conflict mitigation should also begin with implementing the appropriate non-lethal interventions *after* modifying human behavior to effectively reduce hazards of conflict.

Human Safety and Risk Perceptions – As with any other conflict(s), lethal control should follow similar requirements as predation on domesticated animals regarding not only verification, but also non-lethal abatement requirements on the part of the individual(s) reporting the conflict. Such measures should be required prior to any intervention, especially lethal(s).

- Please clarify the following missing but crucial information:
    - How is a concern for human safety verified/determined (given the mentioned criteria)? What evidence or documentation is presented? Where does this discretion lie?
    - What's the criteria for implementing lethal methods in such cases?
    - Why is there no standardized evaluation of risk?
    - The documentation of evidence of risk in such cases, especially prior to the implementation of lethal methods, is essential given the uneducated public may misperceive normal wolf behavior as threatening and may exacerbate the risk through their behavior.

Integrated Wolf Conflict Management

"In determining a conflict management strategy, preference is typically given to nonlethal methods when they are deemed practical and effective. However, non-lethal methods may not always be applied as a first response to each conflict. The most appropriate initial response to a wolf conflict could be a combination of nonlethal and lethal methods." (p.84) – Please substantiate the claim that the best initial response is a combination of methods. Such a statement is not supported by the scientific evidence, especially when considering the additional harms of lethal methods to wolves, their dynamics, and conflicts. Moreover, this statement should clarify the criteria for determining that a non-lethal method is "practical" and "effective" and if/how those considerations are weighed against the killing of a wolf.

"Other times, such as a farm experiencing chronic depredation by wolves which have been conditioned to non-lethal techniques, the most appropriate strategy may be application of lethal methods alone." (p. 84) – Please present data to substantiate such a statement, perhaps on chronic farms and their husbandry practices, including carcass disposal and other abatement measures prior to any implementation of lethal methods.

"Regardless, it is important to note that no abatement measure, whether lethal, non-lethal, or a combination thereof, has been proven to be 100% effective in eliminating wolf conflict. Decades of experience in addressing depredation conflict Wisconsin have shown that using both lethal and non-lethal abatement techniques is more effective in reducing livestock conflicts than a solely non-lethal approach. Therefore, a fully integrated approach which allows the broadest

range of options to be tailored to each conflict scenario typically offers the most practical and effective conflict reduction program." (p. 84) Our recommendations above regarding requirements of abatement measures, changes in husbandry practices and a combination of non-lethal methods will likely mitigate instances of use of lethal methods, are based on the most recent scientific literature, and have yet to be implemented. Hence, we propose such requirements be incorporated if striving for the most practical and effective conflict mitigation program. Given it goes against the established body of scientific evidence cited above, the department should also present data of those decades of work to substantiate the claim above that a combination of methods, rather than non-lethal methods implemented first and foremost, works best for conflict mitigation.

'The highly selective lethal removal of individual wolves or wolf packs by governmental agencies is considered by many professional biologists to be an important part of recovery and conservation programs for wolves (Boitani 2003, Breck and Meier 2004). David Mech wrote, "lethal control will remain the ultimate means of curbing wolf damage to livestock and pets," and, "direct lethal control is still usually the only practical course under most conditions" (1995). The Wildlife Society stated in their technical review of the restoration of wolves in western North America that, "control of wolves preying on livestock and pets is imperative and should be prompt and efficient if illegal killing is to be prevented and human tolerance of the presence of wolves is to be maintained" (Peek et al. 1991). A more recent review of large carnivore management by The Wildlife Society in 2012 stated, "…a large share of the North American public tolerates their presence (large predators) and realizes that management (harvest/agency control) at some level is at times necessary" (Peek et al. 2012).' (P. 84) – These statements present outdated scientific evidence, now >20 years old, that has been debunked by the best available and most recent science on the effectiveness of non-lethals over lethal methods as well as evidence suggesting lethal methods do not increase tolerance, with evidence from WI and beyond (e.g., Hogberg et al. 2015, Louchouarn et al. 2021, Santiago-Ávila et al. 2020a, 2022a). It does not inspire trust in the department's scientific expertise or lack of bias towards wolves that such evidence promoting stronger protections and against lethal methods is omitted, while contrary, older and less robust evidence is foregrounded and presented as evidence for basing policy on.

Wolf Population Health and Captive Wolf Management

This section promotes a cursory and unscientific and reductionist understanding of wolf 'health' as only concerning disease prevalence and transmission. This understanding of 'health' runs contrary to most interpretations that include other physical, mental and social aspects relevant to sentient, conscious and social beings such as humans and wolves. For example, the World Health Organization defines 'health' as "a state of *complete physical, mental and social wellbeing* and not merely the absence of disease or infirmity". We see no reason why such a definition would not apply to wolves given their similar internal and social capabilities (see evidence presented above and reference list). We advance that such an understanding would be grounded in better and stronger inference science, and would certainly consider the harmful effects of lethal methods on wolves as individuals and as a population.

Section 4: Wolf Management in Wisconsin: From Recovery to Sustainable Management

"The following section strives to formalize a path forward which supports a healthy wolf population and the benefits therein while minimizing wolf-related conflicts." (p. 98) – Given the evidence presented above, we believe the plan fails to support a "healthy" wolf population (their 'wellbeing' as individuals and population), although arguably a sustainable one, or to promote policies that will minimize wolf-related conflicts, given the emphasis placed on recreational killing opportunities (used for conflict mitigation, which runs contrary to the scientific literature) as well as the lack of requirements for abatement and non-lethal measures that are more effective and considerate of wolf wellbeing.

Wolf Harvesting Zones

The department should explain the justification and science relevant to this type of density 'zone' management. The department seems to assume that lower zonal densities of wolves will lead to less conflicts (Zones 3 and 4, and 1A and 4A) without providing scientific evidence on the matter. Moreover, the approach ignores the large body of scientific evidence indicating that lethal methods and especially indiscriminate killing are ineffective and potentially counterproductive at mitigating conflicts (see prior comments and reference list below). There is some superficial mention of such literature and conclusions in the plan (which should be improved), but such science is never applied to conflict policies. This also contributes to the erroneous perception that objectives A ('Ensure a healthy and sustainable wolf population to fulfill its ecological role') and B ('Address and reduce wolf-related conflict') are in conflict, when in fact ample literature has documented how non-lethal methods preserve wolf dynamics while being more efficient at mitigating conflicts (than lethal methods; see above comments and references). Likewise, there is also a lack of justification for managing Zone 6 "at very low wolf densities" (which will already be the case given the mentioned suboptimal habitat) through killing rather than ensuring that *healthy* wolves (see discussion above on the impact of lethal methods on wolf dynamics) are able to persist in these zones (Objective A) while mitigating conflicts (Objective B) through non-lethal abatement measures (see above discussion and reference list). Hence, we find the department crafted a wolf zoning policy without much regard to the weight of scientific evidence and inference relevant to its stated objectives, or without explicitly conveying the trade-offs involved between objectives or user groups (e.g.; see Borg et al. 2016 on how killing affects viewing opportunities), and in a way that will likely increase harms to wolves, domesticated animals and their guardians. Given the clear contradiction of policies with the scientific evidence, such actions by the department could very well be interpreted as placing the *consumptive* interests within Objective C (which are not *all* public interests) above a healthy and sustainable population (A) and conflict-mitigation concerns (B), while erroneously using the latter (B) as justification. In that process, the department is also misinforming the public and failing Objective D ('Increase public understanding of wolves in Wisconsin'). We recommend the department follow the weight of scientific evidence in aligning objectives A and B through mitigating the exploitative component of Objective C, which will also increase benefits beyond ecological ones to a broader public throughout Wisconsin wolf range.

- Subzones 1A and 4A, "However, if livestock conflict becomes reduced over time to lower levels deemed more tolerable, one or both subzones could be deactivated such that it would effectively function as part of the greater zone. Their use may also be restricted if public harvest pressure interferes with site-specific conflict abatement efforts (e.g., wolves becoming 'educated' to trapping efforts and reducing abatement trapping

effectiveness).” (p. 104) Please define the criteria to reach such “lower levels” of conflict for deactivating such zones. It should be noted that indiscriminate killing has been proven to increase the risk of conflicts (see discussion above and reference below), and therefore increasing licenses is not an appropriate means of realizing Objective B.

- Subzones 1B and 2B, “Their use would be intended to respect tribal interests in these areas while also continuing to allow reasonable wolf harvest opportunity.” (p.106) It is discouraging and disrespectful to see this type of ‘respect’ for tribal interests: limiting the killing of their brother and relative to those that live on reservations, while not only allowing, but promoting and attempting to optimize killing opportunities through most of the state. Did the department consider closing such areas entirely to indiscriminate killing? This seems yet another example of the clear and exaggerated priority given in all segments of the plan to providing opportunities for indiscriminate wolf killing throughout the state. Even more evidence of this type of bias is how any reduction in killing opportunity is noted explicitly, e.g., “...initiating an anticipatory subzone closure prior to fully meeting the subzone limit may result in *significant reductions (up to 50%) of reasonable harvest opportunity* in these areas”, when in fact such reductions equal 4-2 wolves. Meanwhile, the plan remains silent on any reductions in ecological benefits or other “values-based” enjoyment given the killing of hundreds of wolves annually through hunts and ineffective lethal methods (e.g., how does harvest affect wolf-viewing opportunities and positive interactions?).

Objective A: Ensure a healthy and sustainable wolf population to fulfill its ecological role
It remains to be seen if this plan ensures a sustainable population, given the many concerns over the new SOM wolf population methodology (see Treves & Santiago-Ávila 2023) and decisions over public killing (hunting/trapping/hounding). What is clear is that it cannot in any way be said to ensure either a ‘healthy’ wolf population or that population fulfilling its ecological role. The plan does not consider a more appropriate scientific understanding of health for conscious, social beings (see comments on wolf ‘health’ in Section 3 and referenced scientific literature on wolf capabilities). Moreover, the plan ignores scientific evidence suggesting that exploited wolf populations will be unable to fulfill their ecological role (e.g., Wallach et al. 2009, Ordiz et al. 2013, Kuijper et al. 2016) or how much value in terms of ecological and “value-based” benefits the public will be sacrificing to the desire for a minority to kill wolves (e.g.; Borg et al. 2016) despite the majority of the public also opposing most reasons to kill wolves.

- Strategy A1, Product A1a and Strategy A2 – the department should include measures of health, such as various cortisol levels (e.g. Bryan et al. 2015, Pereira et al 2022), pair/pack persistence (e.g., Brainerd et al. 2008, Cassidy et al. 2023) and impact of management on such measures (see references in ‘Impact of Regulated Harvest on Wolf Dynamics’, Section 1, above).

Objective B: Address and reduce wolf-related conflict
This objective lacks clear and measurable benchmarks for its stated metrics. For example, what number of farms (suffering predation issues) constitutes “few” when only less than 50 farms are affected annually (of thousands)? Moreover, downward to stable trends in number and distribution of conflicts with hunting dogs seems to rely more in regulating and restricting hounding and hound training than any possible intervention in wolf policy. There should be some acknowledgment that the burden for addressing and reducing conflict with hunting dogs is

primarily on hunting dog guardians, while the state should mitigate such conflicts in the least harmful way rather than killing more wolves in response.

The department also assumes conflict between Objectives A and B given its omission of the scientific literature relevant to how unexploited wolf populations are healthier and are involved in less conflict with domesticated animals (see Section 1 comments and reference list); e.g., stable wolf families deterred by non-lethal methods engage in less conflict than disrupted families (see e.g., Haber et al. 1996; Santiago-Ávila 2018a,b). Such an apparent conflict between objectives A and B is non-existent, given wolves' ecological role as apex predators is optimized along with their wellbeing as individuals and families (see comments on Objective A above), which would suggest mitigating lethal methods to the extent possible, and precluding indiscriminate killing. In dismissing this conclusion, the department falls short in its ability to interpret the scientific literature for purposes of harmonizing and optimizing objectives and, most importantly, for mitigating harm for all involved.

Strategy B1 – Given the body of scientific evidence, all implementation of abatement measures should begin with *required* (rather than "encouraged") changes to husbandry practices (if necessary), followed by required implementation of non-lethal interventions prior to any consideration of lethal methods, so as to optimize objective B (and A).

- Please make available the document 'Guidelines for Conducting Wolf Conflict Management in Wisconsin', which seems unavailable to the public. In addition to making it public, it should also be subject to public comment as part of the planning process.
- Product B1f – see comments above on wolf zoning and how indiscriminate killing is not only not effective, but potentially counterproductive to conflict mitigation. Hence, such a product suggests once again lack of reliance on scientific evidence along with a prioritization of indiscriminate killing. At the very least, certain areas should be maintained free of lethal methods for the purpose of researching the effectiveness of non-lethal interventions in their absence (which may be higher; see Santiago-Ávila et al. 2018a,b; van Eeden et al. 2018a,b).
- Product B1h – any mitigation plan should require first and foremost, rather than "focus on", non-lethal abatement by producers

Strategy B3, Product B3a: Continue to work cooperatively with USDA WS to fulfill wolf conflict management in Wisconsin – We recommend the department provide the agreement with USDA APHIS-WS and seek public comment on it as part of the planning process.

Strategy B5: Continue to research conflict mitigation, prevention measures and develop new techniques for addressing conflicts – Please note the prior recommendation of focusing such research on non-lethal interventions (which are preventive and more effective and reliable than lethals). Moreover, such research should set aside areas where wolf killing is prohibited to successfully evaluate the effectiveness of non-lethal methods in preventing conflicts (e.g., lethal methods focused on conflict areas will confound evaluations in addition to potentially exacerbating conflicts).

Strategy B6: Increase public awareness of wolf conflict program and abatement techniques – Much work is required here given the plan fails to include much scientific evidence, especially in areas related to wolf ethology, wellbeing, effect of management on mortality, and effect of lethal

methods on conflicts which should be resolved to be comprehensive. Without correcting such omissions, the information used by the department cannot be considered accurate, current or comprehensive, and will certainly misinform the public.

Objective C: Provide multiple benefits associated with the wolf population
This objective should include a quantification of the ecosystem benefits of wolves given it does not explicitly and transparently acknowledge or consider the potential lost value of ecological services provided due to wolf killing (e.g., Ordiz et al. 2013). Furthermore, the objective includes indices of satisfaction for hunters/trappers, but not for non-consumptive users whose chance of enjoying wolves is being reduced by consumptive users (e.g., Borg et al. 2016). Such a conflict is not even acknowledged, and it is assumed throughout the plan that an exploited yet sustainable wolf population provides the same ecological benefits and the same levels of non-consumptive experiences (for a broader public) without any supporting scientific evidence, and contrary to some omitted evidence (e.g., Borg et al. 2016, Kuijper et al. 2016, Ordiz et al. 2013, Wallach et al. 2009). Such omission of evidence and trade-offs added to the emphasis on the satisfaction of consumptive groups suggests this objective is meant to optimize the recreational killing of wolves, rather than all values, without an explicit accounting of tradeoffs and opportunity loss with other "user" groups.

- In its discussion of reasons for opposing a wolf season, the department mentions concerns over sustainability and harvest methods. However, it dismisses similarly majoritarian perspectives that convey agreement with the lack of necessity for hunting wolves and grave concerns over cultural insensitivity. Such concerns are not explicitly acknowledged in Strategy C1.

Strategy C1: Provide a well-regulated wolf harvest season consistent with public preferences and management plan objectives

- Product C1a: Utilize public harvest to help manage wolf populations consistent with zone specific objectives – See above comments (e.g., Objective A) on the misguided use of harvest zoning to manage populations and conflicts and the scientific literature that suggests this is not efficient management for ecological benefits (A), reducing conflicts (B) or even providing for broad benefits (C). The department suggests that legal harvest will "provide the primary mechanism to manage wolf abundance and distribution at the landscape scale" without providing adequate and comprehensive scientific evidence for that type of management. For example, why do wolf abundance/distribution need to be managed if the body of scientific evidence suggests they self-regulate and lethal methods are inefficient or counterproductive to conflicts? Where is the scientific evidence supporting this type of management? Again, such prioritization of killing without adequate evidence conveys bias in the plan towards the use of lethal methods, and in particular optimizing hunter/trapper opportunities at the expense of all other objectives or public perspectives. Moreover, it immediately betrays the statement: "Department research scientists should ensure these methods remain based upon the most appropriate and science-based information (see Strategy A2)." (p. 124).
- Product C1c: Develop wolf educational materials and provide such materials to all wolf harvesting license holders – All educational materials should be comprehensive and provide an unbiased and holistic perspective of wolves as conscious, sentient, self-aware, autonomous agents with families.

Strategy C2, Product C2g: Determine the number of licenses to be issued for each zone based upon evaluation of zone-specific harvest rates, method-specific estimated success rates, zone-specific quotas, and timing of past zone closures – First, the department should not be promoting such a harmful activity for domestic animals and wolves, especially given broad public opposition to the practice. If constrained by statute to do so, the department can strive to minimize the quota. To paraphrase a judge in a recent decision on the matter: a quota of '0' is still a number. The department can also severely restrict methods, and limit timing to only the period the zone in question is open.

Strategy C3, Product C3b: Recognize the existence, cultural and bequest values of wolves – Please acknowledge that tribal and non-tribal individuals connect with wolves because they consider them persons and relatives, rather than as a population or types of a species (see comments above). Such views are not reducible to 'spiritual' or 'cultural' values and should be acknowledged and considered. Moreover, please explain how you believe you are giving due consideration to those values when lethal management is explicitly signaled as the tool to 'manage' or 'control' wolves.

Objective D: Increase public understanding of wolves in Wisconsin
Such a goal should incorporate all the included scientific literature on wolf ethology (emotional, cognitive and social capabilities) and agency (Edelblutte et al. 2022), as well as how such capabilities and wellbeing is greatly harmed by killing them. Unfortunately, almost all such scientific literature is missing from the plan, which thoroughly betrays this objective. Moreover, given the emphasis on lethal methods throughout the plan and the various reminders that exploitation can be done sustainably, such omission of scientific evidence suggests a biased plan favoring a particular, instrumental view of wolves *that is ethical rather than scientific, but that is nevertheless presented as comprehensive science* (Treves & Santiago-Ávila 2020; Santiago-Ávila et al. 2018c, Santiago-Ávila & Treves, 2021). Given the above, the plan contains grave ethical and scientific misunderstandings and inadequacies that betray its ability to increase appropriate and holistic public understanding of wolves. More importantly, the department should clarify what it means to "foster public support for wolves" given such glaring omissions of science from the plan. Such omitted evidence would only allow for promoting the narrow, instrumentalized understanding and support of wolves promoted by the plan, which is a biased and unscientific perspective, and contrary to that of the broad public according to the department's latest survey. We urge the department to correct the omission of science relevant to wolves in the plan prior to doing any type of educational outreach.

Strategy D1, Product D1f: Share scientific information and research results via popular media outlets and in-person presentations – To promote transparency, independent review, replication, trust and accountability, scientific information including data, methods and statistical code for all analyses and scientific, peer-reviewed publications from the department should be made available to the public free of charge through the department's website.

Strategy D2: Ensure educational materials are reflective of the latest science and accumulated management experience – We recommend the department include the scientific literature and

topics we have identified as missing from the plan so that its educational materials actually fulfill this criteria (see reference list below).

- Product D2b: Continue to provide Wolf Ecology Courses – Given the scientific deficiencies identified in the plan and department documents, currently the department presents a view of wolf ecology limited to information relevant to instrumental enjoyment, such as ecological and recreational benefits (which a focus on killing), while dismissing relevant science germane to viewing them holistically. To correct such harmful biases, we recommend any course of wolves or wolf ecology begin with an exploration of wolf sentience, sapience and sociability, and address how ecology is mediated through those internal qualities and interests of individual wolves. Moreover, such courses should also include an introduction to the scientific evidence on how lethal methods impact wolf ecology.
- Product D2c: Foster relationships with partner groups to deliver science-based educational materials to the public. – Such a 'product' should include partnering with wolf advocacy groups and tribes for preparing educational materials, given such groups present a more comprehensive view of wolves grounded in ethology, more robust science, and generally include information dismissed by the department or consumptive users (e.g., see comments on Product D2b above).

Objective E: Conduct Scientific Research to Inform Wolf Management and Stewardship
In general for this objective, we recommend the department focus its research on the science we have identified as missing from the plan, such as researching holistic wolf health and wellbeing (beyond disease), how management and interventions affect such health at the individual (e.g., cortisol levels and reproductive hormones) and population scales (e.g., pack persistence, survival, distribution, size), and how to improve humans' views of wolves as individuals from a holistic, rather than instrumental, perspective. Moreover, given how the risk of anthropogenic mortality will permeate the landscape, including deep into core wolf range, if further hunts are held, it seems essential to also research the effect of indiscriminate killing on territory size and population model estimates. We are disappointment with the omission of any research on the impact of lethal methods on population dynamics and size, especially when the current SOM methodology was developed and validated with data from years during which wolves were under full Endangered Species Act protections (see Treves & Santiago-Ávila 2023 for a critique). Nor this section concerns itself with research on how widespread killing will affect ecological influences (research on this topic is not included either). We are deeply concerned about such omissions, especially given lethal management seems the preferred alternative by the department, which give the impression of strong, unscientific bias in favor of such methods to such extent that ecological and evolutionary consequences of such policies are not even considered for research.

Strategy E1: Continue to evaluate and improve methods used to monitor wolf population size and abundance. – Please see the attached critique of the SOM methodology, which discusses several concerns that limit the model's reliability, especially in the context of liberalized killing (Treves & Santiago-Ávila 2023).

- Product E1b: Evaluate the potential effects of variability in territory size on population model estimates – Given how the risk of anthropogenic mortality will permeate the landscape if hunts are held, it seems essential to also evaluate the effect of lethal

interventions on core range, territory size, pack size, and population model estimates. Dismissal of this pervasive and widespread effect suggests bias by the agency on what scientific questions are prioritized, namely those that do not question the use of lethal methods.

- Product E1c: Develop a wolf population estimate independent of the scaled occupancy model to enable comparisons – This should have been done prior to establishing the SOM as the only model, given concerns over estimation in addition to lack of precision of the estimates (Treves & Santiago-Ávila, 2023). Additionally, we recommend that any methods developed strive first and foremost for least harm and be non-invasive.

Strategy E3, Product E3a: Continue to cooperate with universities, USDA WS's National Wildlife Research Center, and the department's Office of Applied Sciences to evaluate and develop new techniques for wolf conflict management – The first step in this path is to update the scientific evidence you and most (if not all) the above organizations are basing wolf policy on, so as to provide unbiased scientific guidance to what is an ethical.

Strategy E6, Product E6a: Publish research findings in peer-reviewed scientific research journals. – To make the science as transparent, replicable and reliable as possible, we recommend all peer-reviewed science from the department be published as open access, with the aforementioned data, methods and relevant statistical code included free of charge, following the hallmarks of strong, reproducible science (Artelle et al. 2018).

Objective F: Provide Leadership in Collaborative and Science-Based Wolf Management in Wisconsin

We have identified a number of shortcomings and concerns, both scientific and ethical, with the current draft that if not appropriately addressed will inevitably degrade trust in the department and hurt its ability to provide either leadership or science-based education and policy. We recommend revising this plan and incorporating the relevant literature and our comments as the first step to providing trustworthy leadership.

Strategy F1, Product F1a: Establish and maintain a department Wolf Advisory Committee that is inclusive of the views of all stakeholders, tribes and partners – Currently, the stakeholder group definitions bias the composition of the WAC in favor of the instrumental concerns of narrow interest groups, which hold views that are opposed to those of the majority of Wisconsin residents who support wolf protections and consider it wrong to kill them recreationally. To correct for this bias in perspective of the WAC, the recommend the department modify the group definitions to separately include 'environmental/conservation organizations' whose mission includes conservation of wildlife and natural landscapes (e.g., The Rewilding Institute, Sierra Club) and 'wolf/animal advocacy organizations' (e.g., Project Coyote, Friends of the Wisconsin Wolf, Alliance for Animals).

Strategy F2, Product F2d: Continue fostering alliances with conservation organizations – We would like to note that the inclusion of Wisconsin Trappers Association (WTA) as a 'conservation organization' conveys an ethical bias in the plan. The WTA is explicitly an interest group invested in promoting a consumptive activity, regardless of their feelings towards conservation. Consumptive use of wildlife does not imply a conservation mission.

ROCKY MOUNTAIN ELK FOUNDATION

February 24, 2023

Attn: Wolf Management Plan Comments
Wisconsin Department of Natural Resources
101 S. Webster St.
PO Box 7921
Madison, WI 53707-7921
Submitted via email: DNRWildlifeSwitchboard@wisconsin.gov

Dear Secretary Payne,

The Rocky Mountain Elk Foundation (RMEF) appreciates the opportunity to comment on the Wisconsin Wolf Management Plan (Plan). RMEF's mission is to ensure the future of elk, other wildlife, their habitat and our hunting heritage. We represent more than 225,000 members nationwide with 23 chapters in Wisconsin. Since inception in 1984, RMEF has conserved or enhanced more than 8.6 million acres of North America's most vital habitat for elk and other wildlife, including nearly 10,000 acres in Wisconsin.

RMEF remains a long-time advocate for state management of wolves, which is in line with the North American Model of Wildlife Conservation. More than 1,100 wolves occupy Wisconsin, stretching across the northern and central portions of the state. Wolves continuously emigrate and immigrate to/from Wisconsin, Minnesota, and Michigan, resulting in a self-sustaining regional population now numbering more than 4,000 and connected to the larger wolf population in Canada. RMEF agrees that the wolf population is fully recovered and encourages additional advocacy to delist wolves and bring them back under state management authority.

With significant interest in helping maintain healthy elk populations in Wisconsin, RMEF offers the following comments specific to the Plan components:

- RMEF appreciates Wisconsin's strong research program to ensure sound management that supports a wolf season framework.
- RMEF understands the approach to avoid numeric population goals in the current plan. However, RMEF suggests continued monitoring to help keep tabs on the distribution and population trajectory of wolves. In addition, following delisting of the species, RMEF recommends revisiting this approach to consider population thresholds for management.
- RMEF recommends consideration of the healthy *regional* population of wolves when setting objectives and in estimating populations; the Wisconsin wolf population is not isolated.
- RMEF expresses concern about the wolf predation pressure experienced by elk, particularly the northern herd. In managing the ecological and social impacts of wolves on prey species, RMEF recommends including information on how elk population demographics and distribution may be altered by wolf behavior.

- RMEF supports inclusion of the post-delisting framework for a future wolf season, in anticipation that hunting will again be available as a management tool.

Thank you for the opportunity to review the draft Wisconsin Wolf Management Plan.

Sincerely,

Karie Decker
Director of Wildlife & Habitat

Re: Safari Club International Comments on Draft Wisconsin Wolf Management Plan, 2022

Dear Sir or Madam:

Safari Club International ("SCI") appreciates the opportunity to comment on Wisconsin's 2022 Draft Wolf Management Plan. SCI supports Wisconsin's efforts to collaborate with relevant stakeholders, including SCI's Wisconsin Chapter, to develop and implement a management plan for wolves. Importantly, the Wisconsin Department of Natural Resources ("DNR") should aim to ensure that wolves do not negatively impact Wisconsin's deer, elk, and other wildlife populations. SCI appreciates that the draft plan contemplates allowing DNR to have the appropriate flexibility for managing an increasing wolf population, including annual harvests once the population is removed from the federal list of endangered species. However, SCI remains concerned that the draft plan does not include a specific state-wide wolf population objective and DNR may be underestimating the current number of wolves throughout Wisconsin. SCI also requests that DNR re-evaluate how it considers public input on wolf management and regulated wolf hunting.

Safari Club International

Safari Club International, a nonprofit IRC § 501(c)(4) corporation, has approximately 50,000 members and advocates worldwide, many of whom live or hunt in Wisconsin. SCI also has members who outfit and guide hunts in Wisconsin and depend on this for their livelihoods. SCI has five chapters in Wisconsin and many more in surrounding states.

SCI has participated in multiple cases involving the federal listing status and management of wolves in the United States. For example, SCI has intervened to defend the delisting of the Western Great Lakes Distinct Population Segment wolves, Northern Rocky Mountains Distinct Population Segment wolves, and Wyoming wolves. E.g., *Humane Soc'y of the U.S. v. Kempthorne*, 579 F. Supp. 2d 7 (D.D.C. 2008); *Defs. of Wildlife v. Hall*, 565 F. Supp. 2d 1160 (D. Mont. 2008); *Alliance for the Wild Rockies v. Salazar*, 672 F.3d 1170 (9th Cir. 2012); *Humane Soc'y of the U.S. v. Jewell*, 76 F. Supp. 3d 69 (D.D.C. 2014); *Defs. of Wildlife v. Zinke*, 68 F. Supp. 3d 193 (D.D.C. 2014).

SCI recently defended the 2020 delisting of gray wolves in the lower 48 U.S. States from the Endangered Species Act ("ESA") lists of endangered and threatened species. SCI believes that the U.S. Fish and Wildlife Service correctly removed wolves from the ESA's protections—recognizing, once again, that gray wolves have exceeded recovery criteria for decades. Along with the National Rifle Association, SCI was the first party to appeal the district court's vacatur of that 2020 rule and continues to participate in the protracted appeal.

SCI has also submitted numerous public comments regarding the federal listing status and management of wolves throughout the United States.

Draft Wisconsin Wolf Management Plan

SCI supports many aspects of the draft management plan. The draft plan appropriately provides for an adaptive management approach. SCI also commends DNR for including in its Objectives, Strategies, and Products various items, such as:

- Maintaining sustainable populations of wolves primary prey:
    - Supporting efforts to manage for healthy white-tailed deer populations;
    - Consideration of elk population objectives in relation to wolf management objectives;
- Utilizing a public harvest season to address human-wolf conflicts;
- Providing compensation for loss of hunting dogs;
- Working with dog hunting organizations to promote wolf conflict awareness and avoidance;
- Providing a well-regulated wolf harvest season consistent with the management plan objectives (which is currently required by law, once wolves are federally delisted);
    - Recognizing that providing a public wolf hunting opportunity is a benefit in and of itself;
    - Utilizing public harvest to help manage wolf populations consistent with zone-specific objectives;
    - Developing educational materials for wolf harvesting license holders;
    - Pursuing administrative rules to establish a designated season for dog owners to train for wolf hunting;
- Supporting science-based wildlife management and collaboration with other stakeholders.

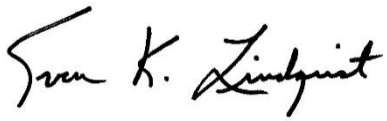
However, the draft management plan should be revised to address several concerns. First, DNR should establish a science-based population objective and manage for that objective. The lack of a population objective undoubtedly causes anti-hunters and others to always advocate for more wolves, regardless of cultural or biological carrying capacity. Without setting a definitive guideline on which to base discretionary management decisions, any effort to stabilize or even reduce the wolf population will be questioned and likely challenged. Establishing a population objective would provide DNR with a specific goal to point to as it makes decisions like setting annual harvest quotas and methods of harvest.

Data in the draft plan shows that Wisconsin's wolf population has been subject to several hunting seasons with significant offtake, but the wolf population has remained robust despite these management efforts. The draft plan should state more clearly that regulated hunting is not a threat to the species. Regulated hunting is fundamental to maintaining the population within management goals and cultural carrying capacity. The draft plan suggests that harvests exceeding a certain percentage (e.g., 30%) would lead to long-term extirpation of wolves in Wisconsin, but SCI questions the assumptions in that model and would like to see more information about that analysis.

Second, SCI disagrees with some aspects of the "occupancy model" used to estimate the wolf population, as they may result in underestimation of the number of wolves in Wisconsin. Although the minimum count methodology may no longer be appropriate given the large number of wolves in the State, relying on volunteer trackers and limiting the average pack size to six wolves for calculating total population likely results in underestimating overall population. Moreover, the model does not count lone and dispersing wolves, despite evidence from hunting seasons that they make up a significant percentage of wolves throughout the State. Of course, any underestimation of the wolf population will likely lead to lower hunting quotas in the management zones. Therefore, SCI encourages DNR to modify its methodology to ensure that chronic underestimation does not hamper effective management of the wolf population.

Third, the draft plan's discussion of human dimensions and public opinions should be revised to give more weight to the impacts and opinions of those who live within wolf habitat and whose lives and livelihoods are affected by wolves. Wolves must be conserved and managed properly, to maintain their populations for future generations to enjoy. But the draft plan should not provide equal weight to the opinions of those who are not affected by the expanding wolf population but might object to or wish to unnecessarily restrict lethal control and regulated hunting. SCI encourages the draft plan to more fully consider the views of hunters and users of other species, like deer, which are affected by wolf populations. The draft plan discusses how wolves are apex predators and can and do have ecosystem-wide effects. That same concept should be carried through the discussion in Section 2, especially Section 2, part 2.

Finally, it is important to discuss and address the concern of those who oppose a hunting program for fear of the risk that "wolves become endangered again." No one wishes for that outcome, including hunters. We all seek to protect and conserve the resource. Modern, regulated hunting has never been responsible for putting any species at risk of extinction, particularly a productive species like wolves (which is also not endangered in other parts of its range, like Canada). But some harvest numbers can look unsustainable to those who do not have the benefit of biological context. Anti-hunting groups take every opportunity to take advantage of lack of public understanding of harvest data.



Accordingly, SCI encourages DNR and State policymakers to stick to science-based decisionmaking when crafting and implementing the plan. The draft plan discusses public perception of wolf hunting generally and of certain methods of harvest. Respectfully, public opinion should not drive DNR decisionmaking regarding wolf seasons; rather, science should steer all population objectives and harvest quotas. Far too often, the court of public opinion

disfavors hunting and certain methods of harvest, especially for predator species, simply because many non-hunters do not understand the need for effective and substantial population management. Such considerations should thus be ignored in relevant decisionmaking.

Conclusion

Thank you again for the opportunity to comment on the Draft Wolf Management Plan. If you have any questions or need anything further, please contact Bee Frederick, State and Local Liaison, at [redacted]

Sincerely,

Sven Lindquist

Re: Sierra Club of Wisconsin's Comments and Recommendations on the 2022 draft Wisconsin Wolf Management Plan

Dear Randy Johnson and DNR Wolf Management Plan Team,

We would like to thank you and your team for the effort developing the 2022 draft Wisconsin Wolf Management Plan. I am submitting these comments on behalf of Sierra Club's 20,000 members and supporters that care deeply about science-based natural resource management. I am also submitting these comments as amember of the Wisconsin Department of Natural Resource's (DNR) Wolf Management Plan Committee.

Overall, we find that the plan centers science, public input, and Tribal engagement- the core tenets of the best way to protect, conserve, and sustain natural resources, incline with our public trust doctrine. Additionally, the Department has done an extensive job incorporating diverse opinions from the Wolf Management Plan Advisory Committee (Wolf Advisory Committee), 2022 public opinion survey, and consultation with the tribes. We want to thank the Department for the broad stakeholder group that made up of the committee, including the incorporation of many of Wisconsin's federally-recognized Tribes.

We also applaud the Department for conducting a very extensive and inclusive scientific survey on the public opinions regarding wolves in Wisconsin (2022). This is a request made by our organization and many others during the Wolf Advisory Committee meetings. It was great to see this suggestion was not only heard but quickly applied. This data shows a sizable shift in public opinions supporting wolves in our state and is strong statistical evidence for the new draft wolf plan.

Overall, we have included some items we would like to have the Department consider for *even further improvements to the draft plan*, overall, we are supportive of the plan as written.

Most importantly, upon review of the draft plan following the comment period, we want to see the Department build on the plan and want to make sure some of the most important features of the plan(listed below) are maintained. Please continue to push for more science-based research in our state as well as wolf co-existence education across Wisconsin.

Important components of the plan that should be kept in the final version::

- **Gals of the Wisconsin draft plan** are right on target - and we fully endorse the outlined objectives and the focus of the plan on the ecological benefits of wolves.

- **Removal of a numeric population goal**: Removing an arbitrary wolf population goal is important to make sure the numbers of wolves are adaptable, so they can be based on best-available science and ecological changes. As written in the plan, the goal should be for the state to have a self-sustaining, self-regulating, and genetically diverse wolf population that maintains connectivity with wolf populations in neighboring states and fulfills their ecological roles.

- **Creation of low limit zones around Tribal lands where the Tribes requested it**: These lands are treaty-protected with documented wolf packs. Making this update is an important and welcome addition to the plan. Ideally, the plan would expand these zones beyond just the few that are listed and ***further*** reduce the limit to one wolf per subzone. The Department should do extensive outreach to all 11 Tribes and make sure they get feedback and accomadate any requests for changes in the plan.

- **Reflection of the public opinions survey** that finds opinions toward wolves have grown significantly more favorable. The plan acknowledges that hunting is rapidly declining, and values are shifting more toward wildlife stewardship versus consumption.

- **Expressed commitment to science and continued research** with partners and acknowledgement that "keystone species such as wolves are an important component of a healthy ecosystem".

- **Education of non-lethal deterrent techniques:** The plan outlines the strategies related to increasing public education related to the implementation of non-lethal conflict deterrent techniques. We especially support collaborative efforts with natural resource educators to develop classroom lesson plans focused on Wisconsin's native wildlife, including wolves.

- **Recommendations to pursue more administrative rules:**
    1. Reduce the window to report wolf kills to 8 hours or less (reduced from the outdated 24 hours in past hunts)
    2. Make purposeful destruction of occupied wolf dens illegal.

Things we would like to see added or reviewed before plan is finalized:

- **Recommendations of legislative changes:** The plan should outline the concerns with ACT 169 and recommend legislative changes be made to the current state statutes so that the DNR is able to make decisions on wolf stewardship in alignment with the goals of the wolf plan.

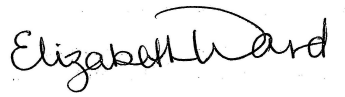
- **In-person registration:** If wolf harvest must occur related to state law, in-person registrationand issuance of wolf harvesting licenses which are valid only in the specific wolf management zone(s) specified on the license should be added to the plan.

- **Better regulation of e hound training on wolves:** The DNR should close wolf-focused hound training activities ***as*** each wolf hunting zone closes. The plan currently would allow hounds to chase wolves for training purposes during the wolf hunting season, across the entire state, until the very last wolf zone is closed. This could go on for months and would interfere with the wolf breeding season and population tracking of which both occur in late winter. Not to mention the disruption this practice causes to other wildlife and humans who are out enjoying nature and/or wolf population tracking.

- **Guidance in plan for next review or update:** there should be a plan for regularly updating the plan (so we don't have another plan that is used for decades). Ideally, the plan should include a provision to update every 5-7 years rather than simply being "valid until it is replaced."

- **Creation of a permanent, ongoing oversight by a stakeholder group AND a science committee** to oversee wolf stewardship in Wisconsin. The stakeholder group must be inclusive and recognize the importance of Tribal oversight. The scientific committee would ensure the best available science and facts are used with less biases to inform decision making.

- **Idenfication of specific metrics that will define successful wolf management in Wisconsin.** Examples should include metrics include pack integrity, average pack size, distribution of CWD in wolf range, the relative distribution of wolves across the state, and genetic connectivity and flow between packs across the state.



- **Prioritized non-lethal deterrents:** The plan acknowledges that there are responsible farming practices and other non-lethal options to reduce wolf and livestock conflicts bu**t** stops short of recommending that the DNR ***prioritize*** these opportunities. This is important because:
    - The best way to stop loss is to prevent it all together. The focus should be on prevention not payment for livestock loss.
    - Scientific studies demonstrate that killing wolves, particularly through recreational hunting and trapping, can lead to increased conflicts, while non-lethal deterrents can be highly effective at deterring conflicts when used correctly.
    - Using the best available science, rather than prioritizing a wolf harvest to help with livestock conflicts, the plan SHOULD focus on non-lethal methods as a win-win.
- **Creation of "Chronic Waste Disease (CWD) zones" on a temporary basis, in areas where new outbreaks beyond the current range occur, like Shawano and Langlade Counties.** It would be unwise to disregard potentially one of the best tools we may have to address this concern. Also worth noting, CWD is a huge issue for many Tribes. The Lac Courtes Orielles Band especially may face a greater threat since it is right on the edge of zone 3. The need for "CWD zones" should be annually evaluated.
- **Population reduction in zones 3 and 4** given that density will naturally be lower in these zones anyway, and reducing it further simply lessens the ecological benefits wolves provide.
- **Separation of private land and public land hunting permits.** Without them, the disproportionate harvest of wolves from prime areas of large public lands is almost certain to continue. It is poor stewardship to hit wolves hardest in the areas that are most suitable for them. In addition, this does affect the Tribes and their ability to exercise treaty rights.
- **Educate about falsehoods about wolf incidents:** The plan seems to include "perceived" harms from wolves as potential justifications for reducing wolf numbers. Wolf attacks on humans in the lower 48 states have never been documented. Wolves take far less than 1% of Wisconsin's livestock and Wisconsin's deer herd is robust. Rather than using "perceived" loss of deer hunting opportunities as justifications for wolf hunting, the DNR should focus on correcting such misinformation, providing robust public education to help residents better coexist with wolves, just as it does with black bears for example. The DNR hosted a black bear coexistence webinar with 800+people in 2022 but has been careful to avoid discussing wolves publicly. Until old myths are confronted publicly, wolves will remain misunderstood and controversial.
- **Include plans for more extensive research:** *We cannot manage what we don't understand.* The plan should recommend significantly *more research* both within Wisconsin and collaboration with Minnesota and Michigan to better understand the Great Lakes wolf population, the CWD connection, non-lethal deterrent techniques for livestock owners, and genetic diversity. Additionally, funding needs to be requested to continue wolf research in support of the wolf plan objectives.
- **Potential impacts of pack destabilization: Studies indicate** human-caused mortality can trigger pack instability in gray wolves. Studies indicate we could be creating the very problems that wolf hunting claims to reduce. The breakdown in social structure can trigger instability and negative consequences to the species by disrupting the breeding behavior, self-regulating mechanisms, and intricate social structures.
  According to a recent scientific study of gray wolves, "Most wildlife studies focus on population size and growth rate to inform management, but relatively few examine species biological processes at scales aside from that of the population. This is especially important for group-living species such as the gray wolf, for which the breeding unit is the social group." Link to study:
  https://esajournals.onlinelibrary.wiley.com/doi/10.1002/fee.2597

In closing, we support the Department's efforts to recognize the importance of dispersal and genetic diversity to wolves' long-term sustainability in Wisconsin. In short, the mere presence of farm and livestock does not recommend hunting and trapping of wolves, especially as best science indicates that recreational killing of wolves serves to destabilize wolf packs and lead to more livestock-wolf conflicts as stated above.

In these mixed areas of Wisconsin, the wisest and most economical course is to keep recreational wolf kills in check while also ***incentivizing, funding and enforcing non-lethal measures to prevent livestock-wolf depredations, focusing on the value of coexistence and improved animal husbandry practices.***

Thank you for your consideration and careful work involving the on-going wolf stewardship of wolves in our state. We look forward to continuing to work with the Department as the plan is finalized and beyond.

Sincerely Yours,

Elizabeth Ward,
Sierra Club Wisconsin Chapter

Re: Superior Bio-Conservancy's Comments and Recommendations on the draft Wisconsin Wolf Management Plan 2022

Dear Randy Johnson and DNR Wolf Plan Team,

We would like to thank you and your team for the effort developing the 2022 draft Wisconsin Wolf Management Plan. I submit our groups' collective thoughts below for consideration.

We find that the plan is a strong step forward in using science and inviting public input; however, it fails miserably regarding respecting Ojibwe Tribal Rights in the ceded territory on all public land. Hunting wolves for them is a cultural afront and disrespectful. Every indigenous nation in the Great Lakes region opposes the slaughter of wolves and supports the recognition of religious and cultural practices which recognize the gray wolf as not only biologically necessary, but also a sacred component of the ecosystem in which they belong.

The Superior Bio-Conservancy is not an anti-hunting organization. Grey wolves are a keystone predator and necessary for the health of the forests. It is wrong to think of them as a game species. We are opposed to the hunting, trapping, and killing of gray wolves on public lands. We are also opposed to hound hunting practices in the Great Lakes region as barbaric sport.

Please continue to push for more science-based research in our state as well as wolf co-existence education across Wisconsin.

Things we support and "LIKE" about the draft plan as written:

- . As written in the plan, the goal should be for the state to have a self-sustaining, self-regulating, and genetically diverse wolf population that maintains connectivity with wolf populations in neighboring states and fulfills their ecological roles.
- **The plan is rightly focused on the ecological benefits of wolves and that wolves are connected to forest health and plant diversity.**
- The plan acknowledges that hunting is rapidly declining, and values are shifting more toward wildlife stewardship versus consumption.
- **There is expressed commitment to science and continued research** with partners and acknowledgement that "keystone species such as wolves are an important component of a healthy ecosystem".

- **The plan outlines the strategies related to increasing public education related to the implementation of non-lethal conflict deterrent techniques.** We especially support collaborative efforts with natural resource educators to develop classroom we lesson plans focused on Wisconsin's native wildlife, including wolves.
- **We support the plan's recommendations to pursue more administrative rules:**
    1. Reduce the window to report wolf kills to 8 hours or less (reduced from the outdated 24 hours in past hunts)
    2. Make purposeful destruction of occupied wolf dens illegal

Things we would like to see added or reviewed before plan is finalized:

It's important to think about landscape scale and prey base ratios in relationship to wolf populations. The forests need wolves to modify and pressure the deer browsing behavior.

Forests are an organism of the land. Wolves act as the immune system of the forest, by changing the forage behavior of the deer to the benefit of the forest structure. From the perspective of the Forest, "The enemy of my enemy is my friend." Healthy forests need wolves to keep the deer in check. (Flagel 2016, Rooney 2015, Waller, Cote, Bradshaw 2016) (Flader 1974)

The ratio of predator to prey populations is a critical balance point in understanding forest landscape health. Wolves work for free and the resulting economic value of having healthy forests benefit all for the future. Predation affects foraging behavior which is manifested over time as an increase in forest biodiversity.

These wolf population densities vary across the north woods within the established ranges. The highest densities are closer to areas that have wilderness attributes (few roads, low population densities and dominant forest canopies). Voyageurs National Park in northern Minnesota for example has wolf densities as high as one for every 10 square miles, they also feed extensively on beavers in that area. (Gable). Wisconsin wolf range densities generally range from one wolf for every 13 to 15 square miles within occupied territories (Wydeven et al 2012).

The Wisconsin current predator/prey ratio is approximately one wolf for every 300-350+ deer (in wolf range). Wolves provide ecological services that provide economic benefit to the health of the north woods. Deer need wolves to keep herds healthy from disease. Wolves have been undervalued by the very State agencies and policy makers that promote themselves as the trustees of our public lands under the Public Trust Doctrine. This is demonstrated by the past State WDNR agencies and policy makers promoting hunting seasons for wolves. Where is the logic in promotion of a hunting season when a single wolf, has a significant role in keeping 9,000 to 15,000 acres of forest healthy, robust, diverse and flourishing? Wolves are the friends of forests. **Perhaps the most valuable regulating element on the Northwood's forest landscape - is the wolf.**

- **The plan should outline the concerns with ACT 169 and recommend legislative changes be made to the current state statutes so that the DNR is**

able to make decisions on wolf stewardship in alignment with the goals of the wolf plan.

- If wolf harvest must occur related to state law, **support in person registration**, and support recommendation that the department **issues wolf harvesting licenses which are valid only in the specific wolf management zone(s) specified on the license**.
- **The DNR should better regulate hound training on wolves.**
    - The DNR should close wolf-focused hound training activities ***as*** each wolf hunting zone closes. The plan currently would allow hounds to chase wolves for training purposes during the wolf hunting season, across the entire state, until the very last wolf zone is closed. This could go on for months and would interfere with the wolf breeding season and population tracking of which both occur in late winter. Not to mention the disruption this practice causes to other wildlife and humans who are out enjoying nature and/or wolf population tracking.
- **There is currently no guidance in plan for next review or update** – there should be a plan for regularly updating the plan (so we don't have another plan that is used for decades). Ideally, the plan should include a provision to update every 5-7 years rather than simply being "valid until it is replaced."
- **There should be permanent, ongoing oversight by a stakeholder group AND a science committee to oversee wolf stewardship in Wisconsin.**
    - **The stakeholder group must be inclusive and recognize the importance of Tribal oversight.** The scientific committee would ensure the best available science and facts are used with less biases to inform decision making.
- **We recommend identifying specific metrics that will define successful wolf management in Wisconsin.**
    - Examples should include metrics include pack integrity, average pack size, distribution of CWD in wolf range, the relative distribution of wolves across the state, and genetic connectivity and flow between packs across the state.
- **The plan acknowledges that there are responsible farming practices and other non-lethal options to reduce wolf and livestock conflicts** but stops short of recommending that the DNR ***prioritizes*** these opportunities.
    - The best way to stop loss is to prevent it all together. The focus should be on prevention not payment for livestock loss.
    - Scientific studies demonstrate that killing wolves, particularly through recreational hunting and trapping, can lead to increased conflicts, while non-lethal deterrents can be highly effective at deterring conflicts when used correctly.
    - Using the best available science, rather than prioritizing a wolf harvest to help with livestock conflicts, the plan SHOULD focus on non-lethal methods as a win-win.
- **The DNR should create "CWD zones" on a temporary basis, in areas where new outbreaks beyond the current range occur, like Shawano and Langlade Counties.** It would be unwise to disregard potentially one of the best tools we may have to address this concern.

    - Also worth noting, CWD is a huge issue for the tribes, and the LCO tribe especially may face a greater threat since it is right on the edge of zone 3. The need for "CWD zones" would be annually evaluated.
- **The state should have separate private land and public land hunting permits.** Without them, the disproportionate harvest of wolves from prime areas of large public lands is almost certain to continue. It is poor stewardship to hit wolves hardest in the areas that are most suitable for them. In addition, this does affect the Tribes and their ability to exercise treaty rights.
- **The plan seems to include irrational, "perceived" harms from wolves as potential justifications for reducing wolf numbers.** Wolf attacks on humans in the lower 48 states have never been documented. Wolves take far less than 1% of Wisconsin's livestock. And Wisconsin's deer herd is robust. Rather than using irrational fears or "perceived" loss of deer hunting opportunities as justifications for wolf hunting, the DNR should instead focus on correcting such misinformation, providing public education to help residents better coexist with wolves, just as it does with black bears for example.
    - The DNR hosted a black bear coexistence webinar with 800+people in 2022 but has been careful to avoid discussing wolves publicly. Until old myths are confronted publicly, wolves will remain misunderstood and controversial.
- **Human-caused mortality triggers pack instability in gray wolves.** Studies indicate we are creating the very problems that wolf hunting claims to reduce. The breakdown in social structure can trigger instability and negative consequences to the species by disrupting the breeding behavior, self-regulating mechanisms, and intricate social structures.
    - According to a recent scientific study of gray wolves, "Most wildlife studies focus on population size and growth rate to inform management, but relatively few examine species biological processes at scales aside from that of the population. This is especially important for group-living species such as the gray wolf, for which the breeding unit is the social group." Link to scientific study

Also submitted via DNR Public Comment Website

Dear Mr. Jonson and DNR Wolf Plan Team:

Thank you for the opportunity to comment on the 2022 Wolf Management Plan. For over 60 years in Wisconsin, The Nature Conservancy (TNC) has collaborated with landowners, businesses, and communities to protect more that 233,000 acres of lands, waters, ecosystems, and species, including threatened species like the Gray Wolf. TNC is also the world's largest conservation nonprofit operating in all 50 states and 79 countries around the globe, and here in Wisconsin we work closely with other environmental groups, sporting groups, agricultural groups, and Tribal nations to implement natural resources stewardship to the benefit of all.

As an initial matter, TNC would like to extend our deep gratitude to you, your team, and all your colleagues at DNR for the tremendous amount of thought and effort put into the 2022 Plan. Your efforts are especially appreciated given the fluctuating protection status of wolves in federal court decisions. It is laudable that such a worthwhile plan was put forward during a time of great judicial and regulatory uncertainty. DNR deserves kudos for focusing on this work amidst often contentious debates.

The Plan's proposal to move beyond a numerical quota for wolf hunting and to instead take a more holistic approach to the issue is most welcome. Numerical

The Nature Conservancy

fax 608/251-8535
nature.org/wisconsin

quotas are an extremely blunt instrument to address the very complex set of issues involved in any future wolf hunt. Adaptive management is a much sounder approach already utilized for critically important Wisconsin species like deer and wolf. Drastically reducing the number of Gray Wolves in our state through hunting without regard to regional distinctions based on the newest available data would be a grave mistake. Without adaptive management approaches, there is also no guarantee that a high-quote hunt would actually result in the decreased depredation events which many cite as the need for a wolf hunt in Wisconsin. Occupancy modeling, volunteer surveys, and an emphasis on combating illegal wolf kills are crucial tools in future management of the wolf population.

TNC partners with many Tribal nations throughout Wisconsin on land Stewardship. Many Tribal leaders have movingly spoken about the spiritual significance of the wolf to their people throughout the Plan process. Some Tribes regard the wolf as a brother and a family member, and this means a wolf hunt is viewed directly as an attack on their family. DNR's extensive efforts to consult with Tribes while formulating the Plan are deeply appreciated, as are proposals to create buffer zones between Tribal lands and hunters. As DNR continues work on the Plan and on the Gray Wolf, it is TNC's hope DNR will consider some commonsense changes to the draft Plan. These changes include, but are not limited to: specific metrics for assessing wolf health and sustainability in each proposed hunting zone, shortening training periods for hunting dogs when a particular zone is open, and practical timelines for hunting and trapping seasons, Plan implementation, and guidance on how the Plan will be funded.

TNC takes a data-oriented, purposeful approach to public policy on wolf hunting as on all other issues which impact wildlife. We remain concerned that there is simply insufficient data to demonstrate that there can be a "safe" hunt of this iconic apex predator, and if the 2022 Plan recommended a specific quota, it is likely TNC would

The Nature Conservancy

have instead recommended a zero quota for a new wolf hunt at this time. This position is arrived not arrived at hastily or lightly, but instead after lengthy consultation with large animal biologists, other scientists, conservation allies, and our nearly 25,000 members in the State of Wisconsin. For this reason, we believe U.S. District Court Judge Jeffrey White's decision re-listing the Gray Wolf as an Endangered Species is correct. The revival of Wisconsin's Gray Wolf population, as others have noted, is a true conservation success story, one that should never be reversed.

TNC again thanks and applauds the Department of Natural Resources for its creation of the 2022 Plan and for the continuing outreach to stakeholders and the public at large to ensure any future wolf hunt provides as much protection for the species as possible. If you have any questions about TNC's views on the Wolf Plan, please do not hesitate to contact me by email or cell at any time.

Alexander R. Madorsky, Associate Director of Government Relations

Submitted by Timber Wolf Alliance

Dr. Erik Olson

First, we would like to commend the Wisconsin Department of Natural Resources for their hard work pulling together this draft Wisconsin Wolf Management Plan. This draft document is a testament to the dedication of the staff of the WDNR and their efforts to properly manage and conserve wolves for both current and future generations.

We believe this draft management plan is a huge step in the right direction. The degree of effort taken to summarize the current literature – while deserving attention in a few spots – is incredible. The amount of new scientific information regarding wolves and human attitudes towards wolves is exceptional. The process used to obtain input from a diverse array of stakeholders to lay the foundation of this plan – solid. The proposed management strategy, outcome-based population management goals, and the proposed modifications to the wolf management zones are supported by Wisconsin citizens, even those in wolf range, and past Wolf Management Plan Committees. We believe these approaches to wolf management to be appropriate, in-line with neighboring states, and based on the best integration of scientific knowledge, human attitude data, and expert knowledge of the system. We strongly support the establishment of extremely low quota zones surrounding tribal reservations. Assuming a wolf harvest season were to occur, we encourage the state to consider closing these zones relatively early for the first few seasons to ensure these zones are not overharvested. The February 2022 harvest raised serious concerns regarding the ability of the WDNR to mitigate overharvest due to policies that are out of managers hands. Once harvest rates are better understood, then we would expect the WDNR to reevaluate the timing of closure for those zones.

Beyond these generic comments of support, we wish to provide more specific comments. A number of groups and individuals have already provided input on the WDNR draft Wolf Management Plan. To avoid replicating much of what other groups have already commented on, we would like to take the opportunity to amplify the voices of one group and one individual. I.e., we wish to reiterate their comments.

We support and wish to amplify the vast majority of comments made by Wisconsin's Green Fire (see attachment). We also support and wish to amplify the public comments of Professor Timothy Van Deelen of the University of Wisconsin-Madison, especially in regards to the role of density dependence in wolf populations.

Beyond those comments, we have a few additional points that we would like to raise.

Page 113: Our main comment – objectives should have definitions for success (i.e., measurable attributes or metrics with thresholds for determining success). These should be realistic and connected to monitoring/data collection efforts that will provide the basis for actually assessing whether or not you are achieving success.

Objective D – we are especially please that the WDNR will interested in working with wolf education organizations such as Timber Wolf Alliance and reinvigorating the WDNR's participation and support for Wolf Awareness Week.

Objective E – we encourage the WDNR to consider joining forces with the tribes, organizations and universities to generate smaller areas in wolf range, where wolves can be monitored intensively using a variety of techniques. The current approach casts a wide net, but misses a lot of the specific details and nuance that can be captured in an intensively monitored population. Northland College, Timber Wolf Alliance, and the Timber Wolf Information Network currently monitor wolf populations fairly intensively in much of Zones 1 and 5 via howl surveys and track surveys. Such intensive monitoring can also be used to ensure population estimates from occupancy modelling are also tracking with different population monitoring strategies at zone scales. Additionally, such studies – if invested in, could provide opportunities to better address some of the other questions highlighted in this section. One additional research question that feels overlooked is pup survival. The WDNR should support collaborative efforts to better assess pup survival and recruitment in the WI wolf population.

We notice that there are no references to the development of a WI Wolf Science Committee. We believe that such a committee would be extremely valuable for helping guide research, building collaborative relationships, and gaining insights that may inform management. We encourage the WDNR to consider reactivating the WI Wolf Science Committee.

References to “Chapron and Treves, 2016” need to also refer to the three separate comments published in response to the publication of that article.

On page 39, “Pre- and post-surveys around the 2012 wolf hunting season in Wisconsin” needs to be qualified by reporting the timing of the “post-“ hunt survey and exploration of how quickly behaviors can be expected to shift.

"conservation through education"

Wisconsin DNR Wolf Management Plan Team –

Our sincere thanks and congratulations to the DNR team that put the extensive effort into composing the proposed plan, and to the all the organizations that took part in the Wolf Management Plan Committee process. We recognize the tremendous amount of work that went into the final product – and all who contributed should be proud.

And we would be remiss if we didn't congratulate the citizens of Wisconsin, for fostering a recolonizing wolf population and allowing it to reach its current robust status. This amazing success story is too often lost in the controversy and rancor that surrounds the gray wolf. It's obvious that there is broad support for the gray wolf in Wisconsin, or we would not have been able to witness this amazing recovery.

We find the plan to be very thorough and well-researched, drawing upon the extensive volume of existing research around gray wolves, and including the always-important social dynamics surrounding this controversial species. It is especially gratifying to see the 2014 public attitude research repeated in formulating the proposed plan – we would hope to see public attitudes revisited once the plan has been in operation for a few years, as a gauge to help guide potential future revisions. We would also strongly encourage a thorough review of the latest science at regular intervals, as emerging tools and techniques continue to shed new light on wolf biology and ecology.

Following are our specific areas of concern - some in agreement with the draft, others offering our suggestions for improvement or refinement.

Population Goal – while undoubtedly this will be the most contentious area of disagreement by those opposed to wolves, it is time to move beyond setting any numerical goals or thresholds. Numerical goals are useful while a population is in the recovery or recolonization phase (as with the current elk reintroduction) but become less meaningful as populations grow past the point of vulnerability and transition to active management.

Wisconsin DNR does not currently manage any species other than elk towards a specific numerical goal – and it is noteworthy that neither of the new wolf management plans for Michigan and Minnesota set any sort of numerical goal. Adaptive management is designed to manage wildlife populations to reduce conflicts and enhance benefits, and this should be the goal of forward-looking wolf management.

Wolf Management Zones – we support the creation of subzones 1A and 4A, to help address these perennial depredation hotspots. While hunting has been shown to not be the most effective tool to address depredation, reduction of wolf numbers in these small conflict areas may be beneficial. We also support the buffer subzones around tribal lands – largely ignored when the initial wolf management zones were established.

We are not in favor of removing western Lincoln County from Zone 2 and making it part of Zone 3. The area was home to the first disjunct pack outside of Douglas County during the early days of wolf recolonization, and it contains important wolf habitat. The number of wolf and hound conflicts in the area supports the fact that it is vigorously defended core wolf habitat. Our organization can certainly attest to the importance of the area to wolves – the New Wood Wildlife Area is our most frequent destination for the wolf-tracking field trip portion of our annual Treehaven UWSP wolf ecology workshop. We recommend that this area remain in Zone 2.

Wolf Occupancy Modeling – we strongly support continuing development of the Patch Occupancy Model (POM) for estimating wolf abundance and distribution in Wisconsin. Recognizing that the model will get better with time, we encourage the DNR to focus additional GPS collaring effort in the Central Forest Region, which has been shown to contain some exceptionally small wolf territories. It is important to understand this distinctive characteristic and apply it towards continual improvement of the POM.

We also support the development of a parallel means for estimating the state's wolf population, using emerging technologies. Genetic analysis is another rapidly evolving methodology for population modeling, and should be investigated for application in Wisconsin, along with any other promising new techniques.

Wolf Conflict Management – we strongly support continuing research and testing of emerging non-lethal conflict abatement treatments. USDA Wildlife Services has a new Non-Lethal Initiative program, and we encourage Wisconsin DNR to take maximum advantage of any new support programs, methodologies, and funding. We've seen some presentations demonstrating the use of drones to disperse wolves away from livestock, and we encourage the department to investigate all non-lethal abatement technologies.

Understanding that sometimes lethal treatments are the best answer, we support targeted lethal removal when necessary, including landowner permits for those who qualify.

Wolf Harvest Management – we strongly support reducing the wolf harvest reporting window to eight hours. On a human-dominated landscape like Wisconsin, it seems reasonable to assume that an individual should be able to report their harvest within this time frame, and this will reduce the possibility of a significant over-harvest as was experienced in February of 2021.

We also support zone-specific harvest tags, which are currently used for black bear and turkey, and which enable the DNR to direct hunter density and hunting pressure most efficiently.

We are opposed to manipulation of permit issuance to maximize hunting opportunity (i.e., length of season). We understand that wolf tag holders have expressed dissatisfaction with early zone closures, however extending the season toward its maximum length creates interference with wolves' natural breeding cycle and makes winter track counts more difficult. There is already significant overlap between winter track counts and coyote hunting – in some cases making it difficult to provide good data. We are also concerned that extended hunting seasons might interfere with the wolf ecology field trips we lead throughout January, part of our education and outreach efforts.

We are also opposed to allowing hound training to occur in closed harvest zones until all harvest zones are closed. Again, this could create unnecessary overlap with winter track counts and in some cases could conflict with the late-winter breeding season – not to mention continuing to chase animals that have survived the open season. We would expect that this scenario might create some conflict between hound training and hound hunting as well, since there would still be hunters in the zone attempting to fill their permits.

We strongly support the use of robust data in establishing wolf harvest quotas, should a harvest season be held again. Harvest quotas should be set based on an annual mortality model that includes all human-caused mortality (including depredation control) and an estimated natural mortality input based on the best available science.

Wolf-Related Tourism – this term comes up often during discussions of the benefits of having wolves on the landscape, but a means to measure this effect needs to be developed. Currently it is easily dismissed by wolf opponents because there is no measure of credibility to this claim.

As those of us who conduct track counts, howl surveys, and camera traps know very well, wolves are cryptic animals that tend to avoid human presence and are not easily detected on Wisconsin's forested landscape.

If Wisconsin DNR is to promote the tourism benefits of having wolves on the landscape, some metric needs to be developed to demonstrate that there is a measurable financial benefit.

Wolf Advisory Committee – we strongly support the formation of the proposed Wolf Advisory Committee, to steer wolf management from the perspective of a diverse group of professional wildlife managers, tribal representatives, and other stakeholders.

We also strongly favor the formation of a separate Wolf Science Panel, made up of wildlife professionals and researchers, active or retired. The panel should include a liaison from the Wisconsin Conservation Congress Wolf Committee.

This group would conduct regular reviews of emerging wolf science and investigate how new discoveries might be employed in Wisconsin wolf management - free of the political dynamics that are inherent in the Wolf Advisory Committee.

In terms of stakeholder groups, we are opposed to wolf research and education groups being commingled with wolf advocacy groups. Our group's mission is to provide wolf education based on the best available science, and we often find our viewpoint at odds with the positions and information espoused by wolf advocacy groups. We would expect that groups like Timber Wolf Alliance and Wisconsin Greenfire share a similar perspective. We would encourage something like a Conservation/ Education/ Research stakeholders' category on the committee.

Wolf Research and Education – we strongly support rebuilding the DNR science team to its level prior to the cutbacks of a few years ago. There are myriad opportunities for continuing research into predator/ prey, predator/ predator, and predator/ livestock dynamics, as well as many other avenues waiting to be explored – all of which can be informative to wolf management going forward.

Collaboration with NGOs in ongoing education is mentioned in the proposed plan, and obviously our organization is in strong support of the concept. We have received somewhat sporadic DNR support for our wolf ecology workshops in past years - it has mostly consisted of listing our workshops on the DNR website. We would welcome any opportunities for increased collaboration in furthering our educational objectives.

Again, thanks to all who worked on the proposed plan, and thank you for considering our comments.

Plover WI 54467

Wisconsin Department of Natural Resources -

Thank you for the opportunity to submit testimony regarding the DNR's draft wolf management plan. **The Wisconsin Bear Hunters Association (WBHA) represents nearly 3000 members in the state** that are dedicated to promoting the rights of sportsmen and sportswomen as well as supporting youth hunting, conservation, and sound wildlife management.The WBHA works tirelessly to ensure that future generations have opportunities to enjoy hunting, fishing, and trapping here in Wisconsin.

The members of the WBHA have been anticipating the release of the wolf management plan for some time now, with hopes for a detailed, thoughtful plan that would adequately lay out a vision for the management of Wisconsin's wolf population. **Unfortunately, the plan as currently constituted falls well short of our expectations and of those of anyone that lives in and around wolves here in the state**.

For any plan to be successful, there needs to be metrics by which one can measure the effectiveness of measures taken to control the population of wolves. The plan as drafted contains nothing that we can see that will give the public and the DNR the tools necessary to measure the effectiveness of the plan. The most glaring omission from the plan is a numeric population goal. **The 1999 plan rightly set a population goal of 350 wolves** based on the social carrying capacity here in the state. **The WBHA strongly supports including this goal in the final plan.**

For any plan to be successful, input from those directly affected must be not only considered, but also incorporated into the plan. **The methodology utilized to gain input from the public was seriously flawed and needs to be reconsidered, giving much more weight to those that live in the wolf range.** While general public opinion towards wolves is nice to know, it is almost wholly irrelevant if individuals have no direct experiences living amongst them.

For any plan to be successful, the process for conflict resolution must contain measures that will result in an end to the conflict. The plan as drafted contains very little when it comes to active measures to reduce conflicts, such as increased harvest rates. **All legal measures to**

control wolf populations, especially when there are conflicts, must be included in the plan.

For any plan to be successful, the rights of individuals must be protected. Hunters in Wisconsin have a right to hunt with dogs, but the plan seems to incorporate biases against hunting with dogs. This is unacceptable. The rights of landowners are also under threat in the draft management plan. **Developing buffer zones outside of recognized tribal reservation boundaries is a taking of private property rights and an abdication of authority by the state.**

While there are many other concerns that the members of the WBHA have regarding the draft plan, we remain resolute in our efforts to assist the DNR in development of a plan that can garner the support of our organization. **However, unless significant changes are made based on the comments above, the WBHA will not be able to support the plan**.

Additionally, there is now a growing effort by anti-hunting groups to ban hunting with dogs in the Chequamegon-Nicolet National Forest. This, if successful, would not only be a violation of Wisconsinites' hunting rights, it would also require the complete reworking of the wolf plan to include much stricter management of the wolf population.

Attached you will find a list of further objections from the Wisconsin Wildlife Federation. The WBHA agrees with the WWF on their objections to the wolf plan.

Thanks for your consideration.

Carl Schoettel
President, Wisconsin Bear Hunters Association

Public comment

1. The 60-day public comment period is not an adequate amount of time to gather input considering the timing of the release overlaps with hunting seasons and multiple holidays. WWF asked for a 90-day comment period.

2. Not all residents have email or computer access in their homes. The DNR should provide multiple and widely distributed announcements of opportunities and methods for public input.

3. There is no means for submitting additional supporting information to the DNR for consideration. The WWF requests the DNR provide the public with an email and mailing address to submit comments and information.

4. The WWF strongly requests the DNR hold public hearings across the state and hold more in wolf-affected zones.

Inclusion/exclusion

5. There is no provision for the inclusion of comments from county and local governments. Many county and local governments have taken positions on wolf population goals and must be included in the process.

6. A functional advisory committee with a balanced mix of impacted stakeholders would vastly improve this process.

Public survey methodology

7. The public survey does not adequately represent those impacted by wolves. Use of county and zip codes to select samples does not accurately reflect those exposed to wolves and impacted by wolves. WWF suggests the DNR seek out those impacted by wolves and place greater emphasis on their perspective.

8. Survey design is flawed. Survey length discourages responses from some individuals. Terminology is undefined and could be seen as biased. Some questions lack balance in positive and negative responses, causing an imbalance in responses. All these features of the survey alienate some individuals, causing them to not respond.

Population estimates

9. Approximately 40% of the wolf tracking units are not tracked to the required three-time standard and not all units are tracked.

This lends itself to under-counting and under-reporting wolf population in those wolf tracking units.

10. Lone and dispersing wolves are not counted in the population model, as

is done in western states. Some states add 12% or 15% to their estimates to account for lone and dispersing wolves. WWF urges lone wolves be included in Wisconsin's population estimate.

11. The DNR is not taking full advantage of public reporting of wolf sightings. The online tool for reporting should be better advertised and the DNR should clarify that personal information is protected and not available as public record.

12. GPS collar tracking provides the DNR with useful information on travel patterns and pack locations for counting. Increased use of GPS collars should be considered.

Conflict management

13. The draft plan is passive and lacks active conflict management for depredations of non-agricultural domestic animals, such as dogs and other pets. Increased harvest is not a method identified in the draft plan to reduce such depredations. Include targeted population reduction in areas of heavy depredation of dogs and other non-agricultural domestic animals. This should include all legal methods of harvest for targeted population reductions.

14. The draft plan does not address a numeric conflict reduction goal. WWF requests a goal be set and included in the plan so effectiveness of methods can be measured.

15. The draft plan appears to have biases against hunting with dogs. Hunting with hounds has the same statutory and state constitutional protections as agriculture and should have equal active measures preventing depredations.

16. WWF opposes the plan wording encouraging low road densities in large tracts of public lands, which is another means to prevent hunting, fishing, trapping, and other public land use.

17. WWF opposes wording that implies hunting conflicts are the fault of the hunter. The draft plan needs to address using population management of wolves as a method to reduce hunting conflicts. Hunters have constitutional rights to hunt lands open to them despite wolf presence.

18. There are multiple systems for sending alerts for livestock, hunting dogs, and nonagricultural animals, but the plan is missing human health and safety alerts. Receiving the same notification with a 4-mile radius map is necessary to help prevent potential conflicts for land users, pet owners, and dog hunters around those areas. The DNR should provide equal notifications for equal protections for all land users.

19. Those who have experienced conflicts with wolves may have traumatic experiences and stresses. The psychological impacts on humans caused by livestock and domestic depredations by wolves is real and needs to be considered. The draft plan ignores the psychological impacts wolf conflicts have on humans and this needs to be addressed in the plan.

Zone changes

20. The plan would create buffer zones surrounding reservations, effectively giving the management of the wolf population on public and private lands outside of reservations to the tribes. WWF opposes the creation of buffer zones surrounding reservations that would take away the rights of private landowners and public land stakeholders. WWF also opposes giving away state wildlife management authority.

21. The agricultural areas in these newly created buffer zones in the draft plan will go largely unprotected and have inadequate protections for pets and livestock.

Landowners will have unequal treatment under the law for which they are protected under the constitution.

22. The zone restructure is now based on wolf occupancy and not based on suitable habitat. The unmanaged wolf population has forced wolves out of prime suitable habitat into inappropriate areas, creating conflicts. Not all areas are appropriate for wolves. WWF requests the zone structure returns to the original science-based, habitat-based zones.

Goal statement/objectives

23. The plan's goal statement does not address where wolves are appropriate. The draft plan needs to take a hard look into what is good for wolves and what is good for humans. Low interactions between the two are best. Wolves should only reside in high-quality wolf habitat and not be managed to the maximum biological carrying capacity. No other species in Wisconsin is managed to its maximum biological carrying capacity.

24. The draft plan implies the elimination of hunting with dogs, which is constitutionally protected. It also implies wolves have more rights to the land than hunters. This narrative is not science-based and all such implications should be removed.

25. Objective B is missing long-term controls for agricultural conflicts. Wolves are known to move "down the road" and create conflicts with just short-term controls.

26. The goal statement or objectives do not address any form of population control. The official position of the WWF is a population goal of 350 wolves in the state. WWF strongly requests the numeric population goal of 350 wolves be maintained in the final plan.

Numeric population goal

27. The draft plan allows for a subjective process for managing wolves. The population goal was established in the 1999 plan due to lack of confidence in a subjective wolf management strategy. There is no accountability without a numeric population goal.

The only scientific analysis of wolf habitat done to date of Wisconsin landscape quantified the social carrying capacity as 350 wolves. The WWF strongly requests maintaining the numeric population goal of 350 wolves in the final plan.

28. For increased accountability the population goal needs to have a timeline for completion. The goal timeline allows measuring of progress towards meeting the set population goal with milestones along the way. The WWF requests a population goal timeline be added to the plan.

Quotas/permits

29. The western states have 13 years of harvest data in establishing quotas to reach their wolf population goals. WWF recommends including this data in the draft plan to aid in setting quotas.

30. Permit issuing methodology should be based on the likely harvest methods used in the season they will be issued.

31. Western states have been unable to reduce their wolf numbers consistently despite high levels of human harvest. As wolf expert David Mech said, “Wolves are prolific, disperse long distances, readily recolonize new areas where humans will allow them, and are difficult to control when populations become established.”

Delisting

32. For lethal wolf conflict control and population management to take place, federal delisting is required. To date the Wisconsin DNR has had no visible involvement in planning, researching, and federal delisting efforts with the USFWS, or with legal representation in delisting efforts. The WWF strongly requests the DNR have a strong and visible presence, and active involvement in all federal delisting efforts that impact Wisconsin and in support of all other states actively working towards delisting wolves in their states.

RE: Comments regarding Wisconsin Wolf Management Plan

Please accept these comments from the Wisconsin County Forests Association (WCFA) regarding the draft DNR Wisconsin Wolf Management Plan.

The Wisconsin County Forests Association (WCFA) represents the forestry interests of the 30 counties in Wisconsin with lands enrolled under Wisconsin's County Forest Law (§28.10 & §28.11). Our member counties collectively manage over 2.4 million acres in Wisconsin, making them the largest public ownership in the State. The counties' partnership with the DNR Bureau of Wildlife Management is critical to the counties' success in providing a wide array of habitat for game and non-game species including the gray wolf.

Specific Comments:

Page iii: County Forest Association. Please change Forest to Forests.

Page ix: Plan Development – This section states 2015 management plan updates were halted in late 2014 due to a change in federal wolf legal status. WCFA has been a Wolf Advisory Committee member since the early 2000's. It is our recollection and opinion that the Committee wished to carry the 2015 plan to completion. However, DNR chose to leave this plan unfinished. If a change in federal protections for gray wolves was the reason for the 2015 plan remaining unfinished, we can only presume the same would hold true for the current plan. The Department has continued with the development of this updated plan even though the gray wolf became federally protected on February 10th, 2022. WCFA recommends the Department acknowledge their decision in halting the 2015 plan update rather than cite a change in federal protections with this responsibility.

Page 24: Identity Groups and Attitudes – "In contrast, negative attitudes towards wolves are more common among those living in wolf range, rural residents, foresters, livestock farmers and hunters." We suggest removal of the group, foresters, in this statement. Should the Department have research or survey information to show foresters hold negative attitudes towards wolves it should be cited as such.

Page 25: Identity Groups and Attitudes – "Though smaller-bodied predators…", "coyotes could serve as a proxy to gauge how urban residents may respond when faced with the impacts of wolf co-existence." Coyotes and wolves serve distinctly different ecological roles on the landscape. Their habitat and prey requirements often differ significantly. Wolves also pose a markedly different threat to human life and safety than coyotes, whether this is based in perception or reality. Unless, the Department decides to adopt coyotes as proxy for co-existence between wolves and urban residents, we recommend removing this section from the plan.

Wisconsin County Forests Association

Page 28: Many times, the plan references increasing "tolerance, support, and understanding", of wolves by the public. While it appears these terms are used interchangeably, we recommend switching the terms tolerance and support to understanding. We believe this brings clarity to the Department's desire of increasing the public's knowledge of wolves through education and outreach while also allowing the public to determine their own tolerance and support for wolves based on their unique individual experiences.

Page 28: "Building partnerships and trust between the various groups interested in the outcomes of wolf recovery will be crucial to ensuring that management of this species reflects the needs and interests of the public and is grounded in science-based decision-making." We believe this to be a core statement of the plan and if adhered to, will guide the Department and Wolf Advisory Committee to desirable outcomes.

Page 99: Implementation of Wolf Management Goal: "The first step specific to harvest recommendations should typically be determining the zone-specific population objectives i.e., given the current conditions in this zone and prevailing scientific knowledge, will increasing, maintaining, or decreasing the wolf population in this zone be most likely to complement efforts to improve or maintain satisfactory overall progress towards plan objectives?" We recommend separating this thought into multiple sentences as it is difficult to read and understand. Please see the follow text for our suggestion. "The first step, specific to harvest recommendations, should be determining the zone-specific population objectives given the current conditions of this zone and prevailing scientific knowledge. Efforts to improve or maintain satisfactory overall progress towards plan objectives may be achieved by increasing, maintaining, or decreasing the wolf population in this zone."

Page 102: Objective D: "fostering public support for wolves through education". We recommend changing the words "support for" to "understanding of". We believe it is important to provide the public with accurate and up to date information through education and outreach, thus increasing their understanding. We also believe it is important that a public agency then allows the public to determine the level of support or tolerance they wish to exercise without pressures from that public agency.

Page 117: "Some level of wolf-related conflict occurrence will be inevitable given that a wolf population of any size continues to exist in Wisconsin. Therefore, it is unrealistic to expect management actions to reduce conflict levels to zero. Instead, benchmarks by which to evaluate the success of this objective include…", "adequate levels of public support towards wolves…". This statement can appear, to those who experience wolf conflict, disingenuous in its attempt to reduce actual conflict. Increasing support for wolves in and of itself does not reduce conflict. Social science studies have shown that general support for wolves is most likely to occur in people who do not live in wolf range and have not interacted with wolves. It is our recommendation to remove this benchmark in the evaluation of reducing wolf-related conflict.

Page 127: "Further, there are people in the state and beyond who will likely never directly interact with the wolf population, yet may engender a sense of satisfaction, and thereby drawing a benefit, by simply knowing a wolf population exists in the state." This plan states the area of bequest value to be relatively understudied. We recognize the bequest value of wolves in Wisconsin and their spiritual and cultural significance to both tribal and non-tribal individuals. For this reason, we recommend the Department highlight this area for future research as applied directly to wolves in Wisconsin.

Wisconsin County Forests Association

Page 140: “Benchmarks by which to evaluate success towards this objective include, but are not limited to…”, “fostering public support for wolves…” As stated previously in our comments, we recommend replacing the word support with understanding. While support may occur through public education, we believe it is important to allow individuals to develop their own opinions through their life experiences and information consumed.

We are happy to discuss any of our comments and thank you for the opportunity to review and provide feedback on the draft Wisconsin Wolf Management Plan.

Sincerely,

Rebekah Luedtke
Executive Director

Public Comments for the draft Wisconsin DNR 2022 Wolf Management Plan
(February 16, 2023)

The Wisconsin Animal Protection Society (WISAPS) appreciates the opportunity to submit public comments regarding the draft Wisconsin DNR 2022 Wolf Management Plan. We will use the format offered by the DNR, on its website, noting our "likes" and "dislikes," and highlighting portions, (in bold).

Thank you for spending the considerable time and effort required to create such a thorough and comprehensive plan! As the Humane Society of the United States suggests, in their comments, we feel that the plan should include a provision that it be **updated at least every five to ten years.**

Initially, we must point out that **WISAPS opposes the intentional killing of wildlife by humans**. Applying the terminology referenced in the plan, our "wildlife value orientation" would be that of "mutualism." As mutualists, we believe that "humans have a moral obligation to treat wild animals with respect," and that "wildlife and humans are part of one community." (Plan, page 25).

We wish that the plan would be **ethics-driven**, in addition to its being "science-driven," and that the DNR would recommend that state law be changed so that it does not require a wolf hunting season when gray wolves are de-listed from the Endangered Species Act. Population control is no more a justification for killing wolves than it would be for killing humans. Needless to say, we are concerned with the DNR's use of the word, "harvest," for killing wolves. Referring to the killing of wild animals as a "harvest" has become a popular way to disguise or soften the appearance of the act of killing an animal.

WISAPS encourages the DNR's exploration of **additional funding options**, as the plan suggests, in Product B4d, "to prevent the need to prorate wolf damage claims." Additionally, the DNR should explore the request for **donations from conservationists who oppose hunting and trapping.** This could be similar to the sale of the Endangered Resources license plate. Alternative funding options would lessen the reliance upon funding from the sale of wolf hunting licenses and permits.

While we appreciate the plan's reference to the pursuit of administrative rules to limit the time period within which dogs may be trained for wolf hunting activities - by designating a season - we wish the department would pursue regulations or rules ***prohibiting*** **the use of dogs to hunt wolves**. (Product C2h, p.127).

With regard to **livestock depredation**, the **Minnesota Wolf Management Plan**

2023-2032, refers to **insurance**, stating: “Alternative approaches to mitigate livestock depredation, such as insurance and cooperative damage management programs, exist and should be considered among the suite of tools to incentivize coexistence of livestock agricultural practices and wolves, and to equitably distribute the costs of this coexistence.” (*See*, Minnesota Wolf Management Plan 2023-2032, p. 27). The DNR may want to explore insurance options and requirements, if it has not already done so, in order to reduce the government’s depredation expenditures.

(Note: Pages 129 and 136 of the plan are both misnumbered as 140).

Likes and Dislikes.

Like

● The plan’s attention to **long-term stewardship and sustainable management** of wolves in the state. (Executive Summary, p. iv).

●Section 1: Gray Wolf Biology, Ecology and Population Dynamics. (Begins on p.1).

●Section 2. Human Dimensions and Cultural Significance. (Begins on p.22).

●Historical Overview of Wolves in Wisconsin. (Begins on p.45).

● “**Building partnerships and trust** between the various groups interested in the outcomes of Wolf recovery will be crucial to ensuring that management of this species reflects the needs and interests of the public and is grounded in science based decision-making.” (p.28).

●“Population management objectives have been developed by the department, based upon.....along with **input from Wolf stakeholder committees and consultations with tribal partners.**” (p.69).

● “The primary **non-lethal abatement methods** implemented at conflict sites, particularly livestock depredation sites, include visual and auditory harassment tools, predator-proof and electric fencing, and alteration of animal husbandry practices (Figure 24). Visual and auditory harassment tools include Fox Lights, scare radios, turbo fladry, and Radio Activated Guard Boxes (RAG Boxes). Predator proof fencing is woven wire fencing that is 75” tall with a 42” horizontal apron and electric fencing (scare wire) is typically a single strand electrified wire approximately 8” off the ground below the bottom strand of an existing barbed-wire fence but may include other configurations. Alteration of animal husbandry practices is implemented by the livestock producer and may include moving livestock to a different pasture, night penning livestock, proper livestock carcass disposal, increasing vigilance, and/or the use of guard dogs.” (p.77).

● “In determining a conflict management strategy, preference is typically given to **non-lethal methods** when they are deemed practical and effective.” (p.84).

● ”In addition to onsite conflict management, the department’s Wolf conflict program also focuses on **proactive public education efforts designed to promote coexistence with wolves and prevention of negative interactions**.....The department and USDA WS have also worked with farming and ranching organizations to host training sessions designed to discuss animal husbandry practices, fencing, carcass management, and agency implemented non-lethal wolf conflict deterrents.” (p.85).

●”An **alternative to numeric population goals** is to prioritize management actions in response to existing conditions as observed in the field and scientific data. This approach strives to find an effective balance between potentially competing objectives associated with wolf management i.e., facilitating wolf-related benefits while minimizing wolf-related conflicts.” (p.97).

●Goal Statement. “The goal of this Wisconsin Wolf Management Plan is to effectively balance the tradeoffs between the following key objectives: • Ensure a **healthy and sustainable wolf population** to fulfill its ecological role (Objective A) • Address and reduce wolf-related conflict (Objective B) • Provide multiple benefits associated with the wolf population (Objective C) In support of these primary objectives, the plan also strives to:
• Increase public understanding of wolves in Wisconsin (Objective D)
• Conduct scientific research to inform wolf management and stewardship (Objective E)
• Provide leadership in collaborative and science-based wolf management in Wisconsin (Objective F).” (pp. iv, 98).

●Implementation of Wolf Management Plan Goal. “To effectively implement the plan goal, the use of a formal yet adaptable approach to evaluating objectives and guiding decision-making is recommended. This process should be **values-based**, **informed by science,** and include routine evaluation aimed at measuring progress towards management plan objectives (Figure 33). This plan recommends **engaging the department’s Wolf Advisory Committee in the process to annually assist** in reviewing data, metrics and trends related to existing conditions on the ground in each wolf management zone. It is recommended to evaluate conditions in each zone against each plan objective based upon the information contained in the objective’s definitions and guided by zone-specific priorities.” (p.99).

●Product B1d: “Continue to evaluate chronic conflict sites to determine the suitability of **permanent fences** as long-term solutions for preventing conflicts. Chronic conflict sites are defined as those farms which have had verified wolf depredation in two or more years in the past five-year period. Addressing depredation on chronic farms is recommended to remain a priority, including evaluation of permanent fences as

long-term solutions when feasible." (p.117).

●Product B4d: "**Explore additional funding options** to prevent the need to prorate wolf damage claims. If approved depredation claims exceed the funds available in a given year, claims must be paid on a prorated basis per state law. Although this scenario has not occurred to date, it remains a possibility, particularly in years without the sale of wolf harvesting licenses or preference points. Therefore, the plan recommends that the department explore additional funding options to attempt to minimize the likelihood of this scenario." (p.120).

●Product C1d: Continue to **exclude 'reservation wolves' from harvest** consideration when developing wolf harvest quotas. (p.124).

●Strategy C3. **Non-consumptive** recreation and tourism. (p.127).

●Product D2b. **Wolf ecology courses.** (pp.130, 131).

●Product E3c.To **reduce hunting dog deprivations** by wolves. (p.134).

●Objective F: "Provide Leadership in **Collaborative and Science-Based Wolf Management in Wisconsin**. ..... This should include ample opportunities for public input and engagement, engagement and consultations with tribal nations, and collaboration with other government and university partners." (pp. viii, 136; misnumbered in plan as p.140).

●Strategy F1: **"Utilize the department's Wolf Advisory Committee to assist in implementing the Wisconsin Wolf Management Plan.**" (p.136; misnumbered in plan as p.140; emphasis in original).

●Product F1a: **"Establish and maintain a department Wolf Advisory Committee that is inclusive of the views of all stakeholders, tribes and partners."** (Begins on p.136; misnumbered in plan as p.140; emphasis in original).

● "Stakeholder Group Definitions:....Wolf Advocacy/Education Organizations: Organizations whose mission includes ensuring the **humane/ethical treatment of wildlife** in Wisconsin, specifically promoting the continued use and advancement of educational tools to increase the public's understanding of wolves and fostering wolf-related coexistence." (p.137).

●Product F1b: **"Ensure communication with and among the department's Wolf Advisory Committee is timely and sufficient to support representative input and effective wolf management decision-making processes."** (Begins on p.137; emphasis in original).

●Product F1c: **"Convene the department's Wolf Advisory Committee at least annually and regardless of listing status."** (p.138; emphasis in original).

●Strategy F2. Support **science-based wildlife management**.. (p.138).

●Product F2d: "Continue fostering **alliances with conservation organizations**." (pp.138,139).

Dislike

●Objective C: " .....providing sustainable **harvest opportunity** via a regulated wolf season (within department authority)...." (p.123).

●Strategy C1: "Provide a well-regulated **wolf harvest season** consistent with public preferences and management plan objectives." (p.123).

●Product C1a: "**Utilize public harvest** to help manage wolf populations consistent with zone-specific objectives." (Begins on p.123).

●Product C1b: "Continue to support the Wisconsin Cooperative **Trapper** Education Program. The Wisconsin Cooperative Trapper Education Program (WCTEP) is jointly administered by the Wisconsin Trapper's Association and the department to provide quality trapper education to individuals wishing to pursue trapping or learn more about the activity." (p.124).

●The inclusion of the Wisconsin Trappers Association in the list of *conservation* organizations, contained in Product F2d, along with the Timber Wolf Alliance (TWA), Timber Wolf Information Network (TWIN), and the International Wolf Center (IWC). (pp.138,139).

We would like to note that **trapping is an inherently violent practice**. Traps that are used, including body-gripping traps, are inhumane devices that inflict great pain and suffering. The traps are designed to crush animals in a vice like grip. (*See*, Fur Free Alliance website). In a letter to Congress, (in 2016), Dr. Collin Wolff, a **board-certified veterinary surgeon**, wrote: "The undeniable truth is these bone-crushing devices are inherently indiscriminate and inhumane." Each year over 5 million wild animals are caught and killed in wild traps, mainly in the U.S.,Canada and Russia. (Fur Free Alliance).

●"Product F2e: "Apply for CITES (Convention on International Trade in Endangered Species of Wild Fauna and Flora) authority." (p.139).

Thank you for considering our comments. We look forward to any opportunity to work with the Wolf Advisory Committee, in the future, as a stakeholder. The Wisconsin

Animal Protection Society is a Wisconsin, non-stock corporation. For more information please see our website at: wisaps.org.

Sincerely,

Mark Silverman

RE: **Wisconsin Cattlemen's Association Comments on Proposed Wisconsin Wolf Management Plan**

Dear Sir or Madam:

I am writing on behalf of the Wisconsin Cattlemen's Association (WCA) to provide our comments and concerns on the Department of Natural Resources' (Department's) Draft Wisconsin Wolf Management Plan (the "Plan").

The WCA is the state trade association representing Wisconsin's beef producers. Our mission statement is, "To promote the Wisconsin beef business through advocacy, leadership, and education." We are deeply concerned about the proposed Plan and its potential to exacerbate the increasing numbers of conflicts between wolves and livestock in our state and perpetuate flawed abatement techniques that are preventing farmers from adequately addressing and managing problem wolves in Wisconsin at great personal economic and psychological expense.

WCA Urges DNR to Only Encourage Wolf Populations in Areas of Wolf Habitat. Wisconsin is home to some prime wolf habitat. However, not all land in Wisconsin is suitable or appropriate for wolves. We support the management of wolves in high quality wolf habitat areas, but we oppose the concept of simply managing the wolf population to the highest number of animals that the State can support on any landscape. No other species in Wisconsin under the Department's management is managed in this way. This is detrimental to both wolves and to our farmers who are also using agricultural lands to support livestock grazing in open areas and on agricultural lands.

WCA Supports a Wolf Population Goal of 350 Wolves. Wisconsin has far exceeded its goal for a sustainable and recovered wolf population. As a result, we are seeing devasting effects on Wisconsin farmers. When the DNR analyzed what a sustainable wolf population would be for Wisconsin, they wrote in Wisconsin's 1999 Wolf Management Plan that they sought a population recovery goal of **350** animals.[1] We are perplexed as to why the Department has not included a numeric wolf population goal in this Plan. Is the Department's plan to manage this species or to just create an environment in which it cannot be managed? How is an unlimited number of wolves in Wisconsin a management goal? We strongly urge the Department to set a numerical standard that is based on science and habitat that the State can support and manage the wolf population according to that goal. We believe 350 wolves is an adequate goal.

[1] Wisconsin Wolf Management Plan, October 27, 1999 (https://dnr.wi.gov/files/PDF/pubs/ER/ER0099.pdf).

WCA Opposes the Proposed Buffer Zone. The Plan creates new buffer zones surrounding tribal lands. There is agricultural land within these buffer zones that will become even more vulnerable to wolf depredations if these buffer zones are created. This is private land that should and must be afforded the same protections under the law as other private lands under this Plan. This is unnecessary and will only harm Wisconsin livestock farmers further.

Conflicts with Livestock are Growing - Wolf Depredations are Costly - Wisconsin Farmers Need Improved Conflict Management Tools. Wisconsin farmers need an effective way to protect their livestock from depredating wolves and an effective mechanism to manage the population. The Plan correctly acknowledges that as the wolf population has grown in Wisconsin, so have livestock conflicts. We also appreciate that the Plan recognizes that, "Even though the total number of farms and livestock involved in wolf depredation and harassment incidents across Wisconsin are numerically low, the costs to individual livestock producers can be high, particularly in areas of chronic depredation activity. Direct losses of livestock due to depredation are conspicuous and economically significant; however, in some cases this metric underestimates the total economic impact because it does not consider the non-depredation impacts. Shelton (2004) suggested that the value of depredated livestock from predators is the "tip of the iceberg" concerning the actual costs that predators can impose on afflicted livestock producers." Pg. 74.

Not only do acts of depredation increase stress to farmers and their families, in some cases triggering severe mental health concerns. But they also consume valuable time and negatively impact a farmer's bottom line. Depredations are quantifiable and measurable factors that can be charted and accurately determined. Wolf damage also includes unquantifiable factors that cattle and other livestock experience from stress due to increased predatory pressures such as loss of pregnancy; reduced pregnancy rates; decreased rate-of-gain; changes in calving/birthing procedures due to the unsafe nature of leaving pregnant livestock to give birth in pastures; increased mowing of tall grasses around pastures; upgrading fencing and other wolf deterrent practices. All of these factors are costly. They can be difficult to measure but are directly related to the increase in the wolf population and interactions wolves are having with livestock in Wisconsin.

However, the Plan's acknowledgement of the direct and indirect impacts to livestock producers in Wisconsin does not help us address or manage wolf-livestock conflicts. The documented non-lethal management tools are not effective in the long term. Wolves may be temporarily deterred by noises or visual stimuli, but they will simply move onto the next farm and come back later. And, while we understand that we are limited to non-lethal management tools while the wolf remains on the Endangered Species List, we respectfully request the Department's immediate assistance and zealous advocacy to appeal to Congress to provide us with some additional relief and conflict management options for Wisconsin farmers.

WCA Asks the Department and the State of Wisconsin to Aggressively Support Federal Delisting of Gray Wolves in Wisconsin. Under the umbrella of the federal Endangered Species Act, the gray wolf's federal status has undergone extensive changes over the last 20 years. This is not due to the biological or scientific evidence that population numbers have met and exceeded their recovery goals, but rather is due to flaws in the Act that make these decisions prone to politics and legal battles based on procedural technicalities. While the recovery status of the gray wolf in the Western Great Lakes region is repeatedly fought over in courtrooms, Wisconsin farmers are left with no effective way to protect their livestock from depredating wolves and no effective mechanism to manage the population. This should be as unacceptable to the Department and the State of Wisconsin as it is to the farmers who face these challenges on a daily basis. It is time for the Department to advocate for a solution that is workable in our State. We urge you to support delisting of the gray wolf and return management of this species to the State of Wisconsin.

Thank you for your time and attention to these comments and concerns.

Sincerely,

Brady Zuck, President
Wisconsin Cattlemen's Association

Position Statement on:

Wisconsin Department of Natural Resources' Draft Wolf Management Plan

By the
Wolf Issues Committee
Of the
Wisconsin Chapter of The Wildlife Society (WCTWS)

To:
Randy Johnson, Large Carnivore Specialist

WI DNR, 107 Sutliff Ave., Rhinelander, WI 54501

Dear Mr. Johnson and the WDNR Wolf Plan Team:

Congratulations on the tremendous achievement by you and your team in developing the draft wolf management plan. The Wisconsin Chapter of The Wildlife Society (WCTWS) appreciates the great effort in incorporating the latest science while paying careful attention to stakeholder concerns, cultural issues, and the public's attitudes toward wolves in Wisconsin obtained using the latest comprehensive attitude survey. The Draft Wisconsin Wolf Management plan (dated 11/09/2022) aligns closely with the guidelines set by The Wildlife Society Issue Statement on "*Wolf Restoration and Management in the Contiguous United States*" (TWS 2017).

The Wisconsin Chapter of The Wildlife Society is made up of 383 wildlife professionals across all career stages (i.e., from students to retired members) working for Tribal, State and Federal agencies, local governments, colleges and universities, and within the private sector in Wisconsin. Together, our membership contains years of experience in supporting sound science in wildlife conservation and management. We offer the following comments in support of and offer recommendations to help strengthen the Draft Wisconsin Wolf Management Plan.

WCTWS supports these elements of the Draft Wolf Management Plan:

- **Removing numeric goals** from the plan is appropriate given current wolf distributions and population numbers. This would create consistency with population objectives also used for deer, bear, wild turkey, and ruffed grouse management. We are pleased to see the Department move away from a population goal of 350 wolves, which is no longer consistent with estimates of potential carrying capacity or public attitudes toward wolves.
- **Redrawing wolf zones across Wisconsin** and the creation of **buffer zones around tribal reservations** will improve management effectiveness and help maintain viable wolf packs on Tribal Reservations and Lands.
- The plan appropriately includes a **rigorous focus on wolf population monitoring,** including using **occupancy modeling** to estimate wolf numbers.
- The plan stresses use of a **science-based management approach** for wolf conservation in an adaptive management framework.
- The plan continues to include **mandatory harvest registration** and **require in-person verification.**
- The plan strongly supports **continued education and outreach efforts.**

WCTWS recommends the following additions and modifications to strengthen the Draft Wolf Management Plan:

- **Core wolf areas in western Lincoln County were added to Zone 3 in transitional wolf range, but should be included to Zone 1,** where there is greater emphasis on ecological fulfillment.
- More **specific metrics of how wolf populations will be managed to achieve goals for each zone should be in the plan,** including average pack size, wolf density, pack turn-over and persistence, dispersal among zones, disease spread, and livestock and pet depredations. Metrics should be quantifiable and be monitored to measure success.
- **The plan needs to include a process to carefully balance numbers of permits issued for legal harvest to assure quotas can be met in a reasonable time period**. The plan should acknowledge trade-offs between satisfaction for a small number of hunters and trappers over a long season versus providing opportunity for many hunters and trappers over a shorter season. Long seasons risk disruption of snow track surveys needed to adequately survey the wolf population and could disrupt wolf breeding activity. Completing seasons by early December would limit disruption of surveys needed to assess the wolf population.
- The plan should **limit the training of dogs on wolves only during periods when wolf hunting or trapping is open in a specific zone.**
- The plan should **include a timeline for implementation.**

- The plan should **include a budget for plan implementation.**
- There should be a **periodic public attitude follow-up survey in the plan**.

Again, thank you for your extensive work on developing the Draft Wisconsin Wolf Management Plan, and thank you for giving the Wisconsin Chapter of The Wildlife Society an opportunity to comment. Good luck moving forward with this new plan in guiding wolf conservation in Wisconsin over the coming decades.

Sincerely yours,

Ken Pemble,

President WCTWS

CC: Randy Jurewicz, Chair,

Wolf Committee, WCTWS.

Position of the Wisconsin Conservation Congress concerning the current Draft Wolf Management Plan January 13, 2023

Without a new Wolf Management Plan, federal law will not allow us to self-manage the state's robust, newly recovered, still growing wolf population. No meaningful controls will be put in place in Wisconsin until a plan is in place, and wolves are again delisted. Over the preceding years, the Wisconsin Conservation Congress and the public which they represent have been frustrated by work stoppages and delays in the preparation of the plan. The final plan is long overdue and has been overdue for many years.

The Wisconsin Conservation Congress opposes the Draft Wolf Management Plan as posted for the following reasons:

Wolf population levels should be monitored, and management prescriptions should be designed to maintain a stated population ceiling. The draft plan proposes to manage wolves based upon measurable criteria reflecting important biological and social factors; a system which has become popular with wildlife managers in and outside of Wisconsin. The Wisconsin Conservation Congress believes that it is important that we track population levels, and that we apply appropriate controls before the anticipated biological and social factors become unmanageable. The committee opposes the reactive management of wolves which is proposed by the draft plan. (The Congress' historic position is that the population ceiling should be 350 wolves.)

The concerns of people living within wolf range must be considered separately and with greater concern than the more idealistic concerns of their metropolitan counterparts. Whether the restored species is tigers in Nepal, elephants in Africa, or wolves in Wisconsin, the burden of restoration is born by the local rural residents, not by the distant folks in Madison, Milwaukee or Waukesha. Wisconsin can do better than that. This plan spends a lot of ink rationalizing support from wolf zone residents and itemizing the benefits already provided to them to offset wolf conflicts. Measurable, documentable thresholds must be established which trigger control actions. Local rural residents must be intimately involved in establishing and monitoring those thresholds.

Areas which are not identified by the current plan as wolf range should not be classified by this plan as primary or secondary wolf habitat, even if those areas are now occupied by wolves.

Re: Wisconsin Conservation Voters Comments and Recommendations on the draft Wisconsin Wolf Management Plan 2022

Dear Randy Johnson and DNR Wolf Plan Team,

Wisconsin Conservation Voters work with our network of over 40,000 members and supporters to engage voters to protect our environment. We appreciate the tremendous work that the Wisconsin Department of Natural Resources' staff underwent to engage stakeholders and the public in developing the 2022 draft Wisconsin Wolf Management Plan.

In general, Wisconsin Conservation Voters generally approves of the Draft Wolf Management Plan, and offers only a few limited comments or recommendations for change. In particular, strongly support these elements of the draft plan, and offer these additional comments/suggestions:

Non-Numeric Population Goal: WCV strongly supports the move away from a specific population goal and towards outcomes-based/adaptive management. This move will allow the DNR flexibility to reach multiple goals and to address the needs of multiple stakeholders. We wonder if the addition of a minimum population goal might strengthen the ability of the plan to meet multiple goals.

Science-based management: WCV encourages the strong commitment to science-based management and the plan to continue a research agenda that aligns with the plan's management goals.

Social Science Research: WCV is particularly pleased that the DNR responded to recommendations of the Wisconsin Wolf Management Plan Advisory Committee to conduct more social science research on attitudes towards wolves in Wisconsin. The current draft management plan seems well-aligned with the 2022 study of current attitudes towards wolves, which notably reflect both continued support for the presence of wolves on the landscape, the desire to move beyond the 350-wolf goal of the 1999 plan, and conditional support for wolf hunting and lethal control of wolves as needed.

Include Education/Awareness in Objective C: A healthy wolf population can also be an opportunity for education in many settings – in formal settings and in the k-12 curricula, and also in

the field and at events around the state. A greater level of education and awareness about the benefits of a healthy wolf population, and of the implications of human-wolf interactions, might be added to the "multiple benefits associated with the wolf population." Education certainly qualifies as a "non-consumptive opportunity." This is addressed elsewhere in the management plan, but adding an education component to Objective C will provide added emphasis for this goal. This would elevate the importance of education and awareness by tying it more concretely to a primary objective of the plan.

Tribal/Citizen/Stakeholder Involvement: WCV is pleased with the emphasis on continued recognition of tribal sovereignty and the recognition of the need for continued collaborative leadership on wolf management, as well as the role of citizen involvement in wolf management in the form of a Wolf Advisory Committee. In addition to the groups designated for inclusion on the Wolf Advisory Committee (on p. 137 of the draft report), we also recommend the inclusion of Wildlife/Conservation Science organizations: Organizations whose mission includes protecting wildlife and habitat through science-based management and ensuring that this is done in a way that is responsive to the general ecological and economic health of Wisconsin's communities.

In addition to the above points, WCV supports the recommendations made by Wisconsin Green Fire to further strengthen the draft report in these ways:

Length of Season: We support adequate issuing of licenses to avoid long extended hunting and trapping seasons. The plan discusses concern about "accelerated zone closures (p. 125)," concern about "low hunter/trapper satisfaction resulting from very short season lengths (p. 126)," and maximizing "hunter/trapper opportunity and satisfaction (p. 126)" through numbers of licenses issued for each zone. There is a tradeoff between allowing a few hunter/trappers to hunt over a long period of time or allowing many to hunt and trap over a short period. A shorter period would give more hunters/trappers the opportunity to participate in the harvest. Long harvest season can be disruptive to snow-track surveys that are done for population monitoring from December through March. Bobcat hunting activities in December and January are already disruptive for trackers. Also, the longer hunting/trapping seasons are likely to be disruptive to wolf pack territory maintenance and breeding activity, especially if these extend into late January and February. We feel that numbers of permits should be adequate so that most zones can be closed by early December to minimize disruption of winter track surveys and disruption of normal pack activity and breeding season.

Dog Training: We commend the Department in attempting to develop a regular training period for dogs used to hunt wolves but have concerns about the administrative rules being proposed (p. 127). **We do not support allowing training of dogs on wolves throughout the state as long as any harvest zone is open.** Running dogs after wolves throughout the winter and into the wolf breeding season of late January and February is likely to be disruptive to trackers attempting to survey wolves over winter, and disruptive to wolf pack territory maintenance and breeding activity. We agree that any dog training should begin on the first Monday following Thanksgiving but should be closed when the specific zone is closed to hunting and trapping.

Statutory Considerations: We strongly recommend the WDNR and NRB request statutory changes in the Wisconsin wolf hunting regulations under 2011 ACT169. These regulations limit the Department's ability to fully use an adaptive management approach for managing the state wolf population. This ACT169 has created major opposition to state and tribal wolf management, making it difficult to federally delist and keep gray wolves off the Federal Endangered Species Act. We recommend the statutory changes authorize WDNR, with extensive public input, to determine

when, where, and the methods of take for harvesting wolves, along with setting quotas, harvest zones, and determining numbers of permits. WDNR should obtain authority to determine if and where wolf harvest occur in the state. Improving authority for WDNR will likely improve the ability to keep wolves off the Federal Endangered Species list and maintain state and tribal management of Wisconsin's gray wolf population.

Thank you for the opportunity to provide comment on the draft Wolf Management Plan. We appreciate your service.

RE: Wisconsin Farm Bureau Federation Comments on Proposed Wisconsin Wolf Management Plan

Dear Mr. Johson:

Thank you for the opportunity to comment on Wisconsin's Wolf Management Draft Plan. The Wisconsin Farm Bureau Federation (WFBF) is the state's largest general agriculture organization with over 47,000 members. WFBF represents farms of different sizes, commodities and management styles. WFBF appreciates the department's outreach during the drafting of the plan and the ability to take part in the Wolf Management Plan Committee.

WFBF supports many of the goals and objectives in the Wolf Management Draft Plan. WFBF supports the ongoing efforts of the department to maintain a healthy wolf population. WFBF supports a healthy population of 350 wolves. The 1999 plan established a state-delisting goal of 250 wolves and a management goal of 350 wolves. WFBF supports returning to 1999 management goal for a healthy wolf population. This could be achieved by strong harvest quotas over a number of years.

WFBF supports the reconvening of the Wolf Advisory Committee biannually regardless of listing status. Updating participants with reports by the department on population monitoring, harvest, conflict and other pertinent data would help outreach efforts and relationship building between stakeholders and the department. The soliciting of feedback from a broad spectrum of stakeholders would provide balanced opinions to the department to help inform management decisions moving forward. Without a more balanced plan, it will be difficult for members of the committee to provide objective feedback to the department.

In addition, WFBF supports the continuation of the wolf damage compensation program with strong support for objectives B2a and the related products with strong emphasis on B4b and B4d. The wolf damage compensation program is an essential policy that must continue compensating producers for damages resulting from wolf depredation. Wolf damage is often significant to individual producers in more than financial ways. The loss of livestock and pets can be emotional and taxing. With the success of the wolf recovery program comes the responsibility to protect local residents from an unreasonable level of livestock losses caused by wolves.

Wisconsin Farm Bureau has concerns associated with the draft version of the Wolf Management Plan. Our principal concern, and one we advocated for as a member of the Wolf Management Plan Committee, is the lack of a numeric population goal. The current plan has a numeric population goal of 350 wolves. The draft plan instead favors an adaptive management approach in which a set of ambiguous objectives are set. The lack of a set numeric goal makes setting consistent zone harvest

quotas virtually impossible as these objectives are broadly stated and easily redefined by the department.

Additionally, WFBF takes issue with the expansion of Zone 4 into Marathon County and central parts of the state previously designated as inappropriate habitat for wolves. This area of the state is now designated as secondary range for wolves, greatly expanding suitable habitat for wolves in the state and putting additional farms at risk of depredation. There is no scientific reason behind the zone change and was made simply because wolves had inhabited the area. In fact, the human population has increased in the area raising the chances of wolf/human interactions. This is in direct conflict of the draft plan's Objective B, to reduce wolf-related conflict.

The plan includes the creation of buffer zones surrounding reservations, effectively ceding management of the wolf population on both public and private lands to tribal governments. We oppose the creation of buffer zones surrounding reservations that would take away the rights of private landowners and public land stakeholders. We also oppose giving away wildlife management authority. (Pg 106)

The department excludes 'reservation wolves' from harvest consideration when developing wolf harvest quotas. Creation of subzones around tribal lands increases the wolves DNR can exclude from population estimates. "Reservation wolves" should be included in the overwinter population count so the public has as accurate of a wolf population as possible. (C1d)

Additionally, WFBF has concerns relating to:

- **Vague benchmarks to evaluate the success of reducing wolf-related conflicts. (Objective B)**
    - The draft plan only mentions "benchmarks" by which wolf-related conflicts would be measured but no specifics how what would define success. Minimizing conflicts should be the goal of the plan with specifics benchmarks to measure success moving forward.

- **Lack of long-term solutions for preventing wolf depredation beyond permanent fencing. (Objective B1d)**
    - Permanent fencing is not a solution applicable to many farms facing chronic conflict. Farms facing chronic wolf/livestock conflict are facing large monetary losses and installing permanent fencing is not a viable solution. Instead, the department should increase lethal control methods and harvest quotas in zones with farmers experiencing chronic conflict.

- **Expansion of DNR authority into animal husbandry practices. (Objective B1e/B1h)**
    - The department suggests alteration of animal husbandry practices that may not be conducive to the producer's agricultural interest. WFBF opposes DNR's expansion into animal husbandry practices and would suggest the department broaden the array of abatement options instead. The inclusion of recommended animal husbandry practices assumes farmers are not already utilizing best management practices on their herds. The inclusion of maintaining healthy, well-fed animals and conducting calving/lambing activities near a barnyard is standard animal husbandry. The suggestion to alter this practice shows a lack of understanding of livestock animal husbandry.

- **Development of wolf-related tourism. (C3a)**
    - The department cites the tourism value provided by wolves in Yellowstone National Park. Wisconsin does not have a national park conducive to wolf-related tourism and a majority of wolf habitat is privately owned property. Therefore, this goal is misguided and could increase trespassing on agricultural lands. WFBF requests the elimination of this goal as it is beyond the scope of a management plan. If tourism is generated by wolf activity, it should be market-driven and not an objective of the department. In fact, the hunting of Wisconsin game animals dwarfs any wolf tourism that would be generated and wolf expansion could harm Wisconsin's reputation as a sportsman's paradise. This objective was not a consideration of the Wolf Management Plan Committee and was only mentioned as an option to study for future consideration. Its inclusion in the draft management plan is inappropriate and premature.

- **The continued use of the 2022 opinion survey (Bradshaw et al., 2022) to advocate for wolf expansion.**
    - The survey was not intended to influence wolf management plan implementation but simply as a public opinion survey. The department's use of the survey to justify wolf expansion and protection is inappropriate. The survey identified mistrust of the department by residents within wolf habitat and hunters/trappers, finding many that fit into either category felt their opinions would be ignored. The Wolf Management Draft Plan continues to disregard the opinions of these residents and will only lead to additional mistrust of the department. Without the support of hunters, trappers and rural residents, confidence in the department's management decisions will continue to erode.

In conclusion, Wisconsin Farm Bureau Federation opposes the Wolf Management Draft Plan. Wisconsin farmers support the inclusion of wolves on the landscape and their role in the state's biological ecosystem but wolf management cannot be left to vague management goals without clear definitions for success. This plan will continue to disintegrate trust in the department and waste an opportunity to find agreement among a broad spectrum of stakeholders.

The department should implement an extensive public outreach campaign that includes multiple in-person public hearings located in primary wolf habitat. Wisconsin farmers and rural residents who live with the results of DNR wolf management decisions deserve a management plan that takes their opinions into consideration.

Thank you.

Tyler Wenzlaff
Director of National Affairs
Wisconsin Farm Bureau Federation

Re: Wisconsin Wolf Management Plan 2022, Wisconsin Department of Natural Resources Bureau of Wildlife Management

Dear Mr. Johnson,

I am writing on behalf of the Wisconsin Farmers Union (WFU) to comment on the proposed "Wisconsin Wolf Management Plan 2022" from the Wisconsin Department of Natural Resources Bureau of Wildlife Management. The Wisconsin Farmers Union does not support the listing of gray wolves under the Endangered Species Act. Policy set by our grassroots membership of farmers and rural Wisconsinites supports the management of gray wolves by the Wisconsin Department of Natural Resources. Just as advances have been made in agricultural sciences and livestock management over the last 50 years, humans' understanding of the ecological role and value of many wild species has grown and we appreciate the opportunity to adjust policies and management plans based on information and experience.

Wisconsin Farmers Union supports the full implementation of the DNR's wolf management plan, with the following changes to the current draft to represent the perspective of smaller livestock operators/ farmers.

I. Wolf-Related Conflicts- Wolf/ Livestock Conflict

The percentage of reported conflicts that are subsequently verified to be wolf-related conflicts range from roughly 35-66%. This indicates an area in which public education, both in general and with targeted information to farmers, ranchers, and hunters, could result in a more informed public. Education on how to more accurately identify wolf-related conflict could result in lower costs to the DNR and USDA Wildlife Services in responding to and investigating conflicts.

We recommend future research to guide the specific populations and geographic areas to be targeted by outreach and educational efforts.

II. Non-Depredation Impacts on Livestock

As described in the draft plan, in addition to direct losses of livestock through depredation, the presence of wolves can have a variety of other impacts on cattle/livestock. While wolves very rarely spread disease directly, their presence can cause stress in cattle/livestock which can result in weakened immune responses. As listed, stress can also reduce productivity and cause weight loss, lessening the value in affected livestock. Cattle may be nervous or aggressive after a wolf presence, and re-grouping cattle in cases where they escape pastures can be time-consuming. Loss of fencing and damage to row crops have also been reported.

These non-depredation burdens currently fall on the farmer's shoulders. In an industry with frequently tight profit margins, this impacts the economic viability of farms and reduces economic returns to farms in highly-affected areas.

Wisconsin Farmers Union proposes farm impacts, both depredation and non-depredation conflicts, be more fully analyzed, and at minimum give the ability for non-depredation impacts to be reported for compensation when appropriate.

III. Impacts on Grazing

Other non-depredation impacts are to grazing operations. At times, farmers may be forced to abandon the use of a field or pasture used for grazing due to higher risk from wolves. In many cases farmers are told to move their livestock closer to the barn, in some cases this option is difficult due to limited pasture and a system that is not intended to bring livestock in from alternating pastures every night. In some cases, these actions could endanger operations' Grassmilk and/or Organic certifications.

Those of us who promote rotational grazing and reliance on perennial crops for pasturing livestock are losing ground on the promotion of this husbandry when wolves are involved. We recommend future study around the impacts of wolf management practices on dairy versus beef cattle, as research has shown different impacts on these groups.

IV. Abatement Options

There are tools available to reduce predation on livestock. While some managers are willing to incorporate those into their plans, others may believe they are too expensive or too time-consuming to do so.

Knowledge of various deterrence methods (dogs, fladry, lights, noise, etc.), including costs and effectiveness, needs to be disseminated among livestock managers. Increased awareness and understanding may be sufficient for some managers to implement changes, but for others cost-sharing programs may be deemed necessary, as farmers are already operating under increasingly tight profit margins, especially in this era of high input costs and rising inflation.

Reducing depredation by utilization of more effective deterrence methods could free state and federal monies to be used for other management activities. Perhaps collaborations with various agencies and organizations could be developed to support breeding programs for livestock guardian dog breeds that are more effective at reducing depredations from wolves than the breeds currently available in Wisconsin, the Western Great Lakes Region and other areas supporting wolf populations in the US. Developing breeding programs run by farmers and ranchers could bring in a new source of revenue to those individuals.

V. Acknowledgement of Indigenous Lands

Wisconsin Farmers Union expresses appreciation for the contributions of our Tribal colleagues. We have respect for their status as representatives of Sovereign Nations and believe tribes should have the right to manage the wolf population in their region. We see a great value in working in partnership with our Tribal colleagues on this issue and others.

Despite its challenges, recovery of the gray wolf population in Wisconsin is a success story. The previous recovery goal of 350 animals has been far exceeded. The state of Wisconsin has successfully administered a hunting season to manage the population. WFU calls upon the DNR to continue to implement measures to balance the population, taking into account pack populations regionally. The number of farms with verified wolf depredations has averaged about 30 farms from 2011-2023, with wolf depredations rising to a high of 48 farms affected in 2021. (Figure 22 - page 74) It is clear that management of the population must occur to alleviate this increase in depredation incidents. WFU also recognizes, however, that abrupt shifts in population can upset pack dynamics and increase the potential for predation on livestock; therefore, we call upon the DNR to analyze regions where depredation is occurring and use best practices to address individual incidents.

In ongoing efforts to manage the wolf population in the state, WFU encourages the DNR to continue to include farmers' voices, balanced with other stakeholder groups, when considering shifts in management moving forward.

Thank you for the opportunity to provide comments on the proposed Plan. If you would like to further discuss WFU's position on this matter, please contact Linda Ceylor, WFU DNR Wolf Management representative, via e-mail at [redacted]

Sincerely,

Linda Ceylor

Re: Wisconsin's Green Fire (WGF) Comments and Recommendations on the draft Wisconsin Wolf Management Plan 2022

Dear Randy Johnson and DNR Wolf Plan Team,

We would like to congratulate you and your team on the extensive effort developing the 2022 draft Wisconsin Wolf Management Plan. My colleagues and I on Wisconsin's Green Fire's wolf management team have reviewed the plan and they have helped inform these comments I submit as a member of the department's Wolf Management Plan Committee.

The plan clearly represents a great deal of work by you and your colleagues. While we note some areas of concern and suggested modifications, overall, we find the draft plan to be comprehensive, objective, and meeting high professional standards. The plan represents an extensive review of the scientific literature, background, and carefully planned management strategies that consider the science and the diverse range of views on the appropriate conservation for wolves in Wisconsin. The Department has done an extensive job incorporating diverse opinions from the Wolf Plan Advisory Committee, 2022 public opinion survey, and consultation with the tribes.

We also commend the social scientists for conducting a very extensive, representative, and inclusive survey on the "public opinions regarding wolves in Wisconsin (2022)." WGF member Thomas A. Haberlein especially captures the value of this recent wolf attitude survey:

"Normally I am a pretty critical reviewer. But I have to say I was overwhelmed by the quality of the whole report and particularly the human dimension section. I wish I had been part of it. This truly shows how far the field of Human Dimensions of Wildlife has come since I began doing studies for the Department in the 1970's and in the last three decades since Kellert and I conducted our survey of attitudes toward wolves in Michigan. The 2014 Wisconsin survey received a 59 percent response which was huge (see Stedman et al. 2019 who document falling response rates in natural resources surveys). This high response shows that the questionnaire made sense to the respondents and that follow up procedures were adequate. We can trust these data. The research is further remarkable because it measures change in attitudes between 2014 and 2022. This is rare in human dimensions research and gives a particularly unique perspective. Seldom do we get data on changes over time. The lower 38% response rate in the 2022 survey is good, but consistent with the declines documented by Stedman et al. (2019). Change data are rare in the human dimensions field and we should welcome the insight they give about changing attitudes toward wolves. The Human Dimensions section starts with an excellent discussion of values, and identities the media. This helps put the data in context and should be required reading. Bravo to Ms. Bradshaw."

Throughout this review, I will use the pronoun "I" to refer to specific comments or recommendations directly from me as a member of Wolf Plan Advisory Committee, representing WGF. I will use "We" to refer to general comments, recommendations, and concepts from WGF.

I will initially discuss the aspects of the plan which we in Wisconsin's Green Fire's Wildlife Work Group strongly support, discuss some issues of concern, and include a full review of the documents with edits and recommendations in Appendix A. Any new literature cited will be in the Literature Cited section at the end of Appendix A, but I do not list literature already cited in the WDNR draft wolf plan.

Wisconsin's Green Fire supports the following elements of the current draft Wolf Management Plan:

Wolf Population Goal

The removal of numeric goals from the wolf plan and focuses on ecological benefits and sustainable populations, while addressing conflicts, and providing multiple benefits from the wolf population. Removing numeric goals from the wolf plan is appropriate given their current status and consistent with population objectives with population objectives used for other iconic species such as deer and bears. We support moving away from one fixed goal toward a goal of sustainable ecological function, using adaptive targeted management. The management goal of 350 animals established in the 1999 plan was developed at time when there were 200 or fewer wolves in the state, and best available science based on estimates of suitable habitat and population viability analysis suggested a potential wolf population of about 500 wolves. More recent estimates suggest potential carrying capacity might be about 1242 wolves, and research has demonstrated current wolf populations of 900-1000 wolves are providing many ecological benefits, and attitude surveys show most of the public support current population levels. **Reducing the wolf population to 350 wolves would require removing wolves from 2/3 – 3/4 of wolf range in the state, drastically reducing ecological benefits from wolves, reducing ability of many Indian reservations to support wolves, and likely only having a minimal impact on reducing wolf conflicts compared to targeted controls at depredation sites.**

Wolf Management Zones

- **The designation of wolf zones across Wisconsin**, with exception of some core areas removed from Zone 2 to secondary wolf range in Zone 3 (see below).

- **The designation of Zones 1, 2, and 5 as core areas of wolf range where ecological benefits and population sustainability are the emphasis**. It appears that that harvest rates will be kept low and should generally manage for relatively stable populations near current population levels, except the designated 1a subzone where livestock depredation rates are high. In general, population reductions would normally not be recommended for these zones, unless conflict levels are unusually high**.**

- **The designation of Zones 3 and 4 as secondary wolf range and traditional range** where there is greater emphasis on reducing conflicts and providing multiple benefits from the wolf

WIGreenFire.org
PO Box 1206, Rhinelander, Wisconsin 54501 | Info@WIGreenFire.org

population, but still provide ecological benefits and maintain sustainable populations. Plans to allow reductions, stabilize, or allow increase would vary from year to year depending on levels of conflicts. We urge the Department to avoid drastic reductions in wolf densities, especially if there is a threat of Chronic Wasting Disease near areas of wolf range.

- **The designation of Zone 6 as an area mostly unsuitable for wolves** and placing emphasis on reducing conflict and providing multiple benefits from the wolf population. Wolves will typically exist at low density and their ability to provide ecological benefits are limited.

- **The designation of subzones 1A and 4A as locations allowing more liberal harvests to reduce conflicts in areas with high levels of livestock depredations**. This would eliminate need to reduce a wolf population throughout a large area such as Zone 1, when livestock depredations are mainly focused on only a small fraction of the zone.

- **The creation of subzones 1b and 2b as buffer areas around Indian reservations to better protect reservation packs and core areas by maintaining low harvest thresholds around the reservations**. Such sanctuary areas provide overall benefits for wolf conservation in the region (Mech 2021). If regulations change and WDNR regains authority to determine portions of Wisconsin open and closed to wolf harvest, **we recommend that these buffer areas become 0 quota areas but recognize current regulations does not allow this**. We agree that normal depredation control activities, including lethal controls when wolves are delisted and when appropriate, will continue in these subzone areas.

<u>Wolf Population Monitoring and Research</u>

- **Research on wolf ecology, population dynamics, wolf depredation management, alternate and auxiliary survey methods and supporting additional research by collaborators** to assure that best available science informs state wolf conservation.

- **Greater emphasis on reducing illegal kill rates across the state.**

- **Commitment to using a scientifically informed adaptive management approach** to wolf conservation in Wisconsin.

- **Intense and continued population monitoring, including continued use of occupancy modeling (OM) and volunteer track surveys,** as well as ongoing evaluation of the occupancy modeling system and using other data source to inform wolf management. *

*Wisconsin's Green Fire supports use of OM as a data driven statistical estimation procedure. Occupancy models (OM) have been widely applied and rigorously tested on everything from “beetles to bears” and used not only to estimate distribution, but vital rates of populations (Bailey et al. 2014). Just

WIGreenFire.org
PO Box 1206, Rhinelander, Wisconsin 54501 | Info@WIGreenFire.org

as the previous Wisconsin "minimum counts" method applied, OM estimates the number of wolves on the landscape at a fixed point in time, and both methods can be used to estimate the change from year to year. OM does not include hidden assumptions about mortality, illegal kills, reproduction etc., all of which contribute to the number of wolves estimated.

OM has the distinct advantage of explicitly accounting for differences in detection probability, which minimum counts do not. The OM methodology allows using covariates like weather conditions, habitat, presence of disturbance, etc. to model detection, in a given year and place, and thus accounts for variation that would influence the estimated occupancy. The OM results in estimates with credible intervals, which is not possible with minimum counts. The "wide" credible intervals (CI), which some perceive as a weakness rather than a strength, can be useful for setting harvest limits.

Wolf Harvest Regulations

- **Zone-specific permits that only allow hunters and trappers to harvest wolves in a single zone, and once the zone is closed, the harvest permits are no longer valid for other zones,** but agree hunting and trapping could continue in subzones of a zone, until subzones are also closed**.**

- **Mandatory harvest registration and in-person certification requirements** that should include requirements to provide biological samples as needed for monitoring and research.

- **Commitment to education and outreach efforts and working with partners** to promote educational efforts.

Wisconsin's Green Fire recommends the following changes or additions to the draft Plan:

Population Management

- Western Lincoln County was placed from Zone 2 (core wolf area) into Zone 3 (secondary wolf range). This was the first area occupied by wolves in northcentral Wisconsin after wolves moved into northwest Wisconsin in Douglas County in about 1978-1979. Western Lincoln County was always located in the most suitable wolf habitat in the state in wolf habitat assessments (Mladenoff et al. 2009) and has not been mapped as an area with likely wolf livestock conflicts (Treves et al. 2004, 2011) No livestock depredations have occurred in the area in recent times (Fig. 38, p. 120). **We recommend that this area be included with Zone 1, having a western boundary consisting of Roads, Co.C, WI 102, WI 86, & Co. D (eastern Taylor and southeast Price Counties), southern boundary of US 64, and eastern boundary of U.S. 51.**

- **We recommend outlining how wolf populations in each zone will be managed to achieve goals outlined in the plan** including defining "sustainable population," maximizing the potential for ecological benefits, and controlling the spread of diseases like Chronic Wasting Disease (CWD).

WIGreenFire.org
PO Box 1206, Rhinelander, Wisconsin 54501 | Info@WIGreenFire.org

- **We recommend identifying specific metrics that will define successful wolf management** in Wisconsin. Example of metrics include pack integrity, average pack size, distribution of CWD in wolf range, the relative distribution of wolves across the state, and genetic connectivity and flow between packs across the state.

Harvest management

- **We support adequate issuing of licenses to avoid long extended hunting and trapping seasons.** The plan discusses concern about "accelerated zone closures (p. 125)," concern about "low hunter/trapper satisfaction resulting from very short season lengths (p. 126)," and maximizing "hunter/trapper opportunity and satisfaction (p. 126)" through numbers of licenses issued for each zone. There is a tradeoff between allowing a few hunter/trappers to hunt over a long period of time or allowing many to hunt and trap over a short period. A shorter period would give more hunters/trappers the opportunity to participate in the harvest. Long harvest season can be disruptive to snow-track surveys that are done for population monitoring from December through March. Bobcat hunting activities in December and January are already disruptive for trackers. Also, the longer hunting/trapping seasons are likely to be disruptive to wolf pack territory maintenance and breeding activity, especially if these extend into late January and February. **We feel that numbers of permits should be adequate so that most zones can be closed by early December to minimum disruption of winter track surveys and disruption of normal pack activity and breeding season.**

- We commend the Department in attempting to develop a regular training period for dogs used to hunt wolves but have concerns about the administrative rules being proposed (p. 127). **We do not support allowing training of dogs on wolves throughout the state as long as any harvest zone is open**. Running dogs after wolves throughout the winter and into the wolf breeding season of late January and February is likely to be disruptive to trackers attempting to survey wolves over winter, and disruptive to wolf pack territory maintenance and breeding activity**. We agree that any dog training should begin on the first Monday following Thanksgiving but should be closed when the specific zone is closed to hunting and trapping.**

Plan Implementation

- **We do urge the Department to carefully plan the Wolf Advisory Committee to be representative of the broad range of wolf concerns across the state, tribal concerns, and adequately represent the science needed to properly manage wolves in Wisconsin**. Along with listed stakeholder groups on page 137, **we recommend including Wildlife/Conservation Science organizations:** Organizations whose mission includes protecting wildlife and habitat through scientific and thoughtful management; promoting the use of the best available wildlife/conservation science and management techniques.

WIGreenFire.org
PO Box 1206, Rhinelander, Wisconsin 54501 | Info@WIGreenFire.org

- **We recommend outlining a timeline for plan implementation and revision** and identifying mid-point check-ins to assess the plan implementation process.

- **We recommend including a forecast outlining specific budget** needs to fully implement the actions outlined in the plan in addition to the summary of funding and expenditures for plan implementation.

- We commend the Department for their efforts to assess public opinion on wolves through multiple public attitude surveys. **We recommend that the Department conduct follow-up public opinion survey to gather information on changes in public opinion and assess public perception of zone-specific management strategies.**

Research Recommendations

- While Occupancy Modeling is the current preferred method for estimating wolf numbers in Wisconsin, public acceptance and understanding of the method is still poor. **The Department will need to continue to educate people on OM, provide assurance of data used in the method, and support other surveys and auxiliary data on the wolf population**.

  For example, Figure 16 (p. 50), should show results of OM for 2018 and 2019, showing overlap of 95% credible interval with minimum counts. Such a graphic would help to show how the two survey systems related to each other over a period of three years, demonstrating that OM gradually replaced minimum counts, rather than appearing in one year. Also, the draft wolf plan states that OM was started in 2020 (p. 113), when it has been used since 2018, and research on alternative methods to survey wolves had been occurring for several years.

- **We recommend the following research priorities:**
  - **Monitoring the connectivity and gene flow among Wisconsin's wolf zones and interchange with Michigan and Minnesota**. We recommend genetic research like Reding et al. (2012) on bobcats, or Rick et al. (2017) on wolves in Minnesota.

  - **Inter-state collaboration with Minnesota and Michigan.** There is a strong mixing of wolf populations among these states, there should be a unified research agenda to address management issues as cost-effectively as possible.

  - **Documentation of the role that wolves play in regulating the spread of CWD within Wisconsin.** We encourage the Department to indicate in the Draft Plan that temporary, small-scale, local harvest/research/surveillance zones may be established around newly documented Chronic Wasting Disease (CWD) outbreaks within wolf range. Within these temporary Wolf/CWD surveillance zones, wolf harvest should be kept to a minimum in order to maximize the opportunity for wolves to potentially control CWD expansion.

WIGreenFire.org
PO Box 1206, Rhinelander, Wisconsin 54501 | Info@WIGreenFire.org

These temporary Wolf/CWD surveillance zones would also be focus areas for intensive surveillance and research, to document relationships between wolves, deer, and CWD. Predation as a natural control has a theoretical basis (Wild et al 2011, Brandell et al. 2022), and studies have found other predators such as cougars select for disease-compromised cervids (Krumm et al 2010; DeVivo et al 2017). Removal of infected animals by predators could benefit disease management efforts (Baune et al 2021).

Statutory Considerations:

- **We strongly recommend the WDNR and NRB request statutory changes in the Wisconsin wolf hunting regulations under 2011ACT169**. These regulations limit the Department's ability to fully use an adaptive management approach for managing the state wolf population. This ACT169 has created major opposition to state and tribal wolf management, making it difficult to federally delist and keep gray wolves off the Federal Endangered Species Act. **We recommend the statutory changes authorize WDNR, with extensive public input, to determine when, where, and the methods of take for harvesting wolves, along with setting quotas, harvest zones, and determining numbers of permits.** WDNR should obtain authority to determine if and where wolf harvest occur in the state. Improving authority for WDNR will likely improve the ability to keep wolves off the Federal Endangered Species list and maintain state and tribal management of Wisconsin's gray wolf population.

Thank you again for your tremendous work on assembling this draft Wolf Management Plan. Detailed comments on the plan and literature cited follow in Appendix A below. We look forward to the updated version of the plan, thank you for taking the time to consider our input to the Plan. Please let me know if you have question about any of my comments or suggestions.

Sincerely Yours,

Adrian P. Wydeven,

Appendix A. Comments and recommendations on "Wisconsin Wolf Plan 2022"

P. 1, under taxonomic discussion may also want to cite Nowak (2009) Fain et al. (2010), and Wheeldon et al. 2010.

P. 1 bottom of page *Cervus elphus* should be *Cervus canadensis.* Most wildlife scientists have returned to recognizing elk as a distinct species from the red deer.

P. 2, discussion of genetics could include a statement about recent research in MN, something like the following, "At a finer genetic scale, in Minnesota researchers detected 3 genetic clusters of gray wolves across the state, but these increased to 4 genetic clusters after wolf harvest began (Rick et al. 2017). Similar research may be conducted in Wisconsin in the future, or perhaps across the Great Lakes region as has been done for bobcats (*Lynx rufus*) (Reding et al. 2012)."

P. 2, name at bottom of table 1 should be Stewart.

P. 3, name at bottom of table 2 should be Stewart.

P. 4 would also be useful to show current wolf range across all of North American.

P. 5, 2nd para. "During early recolonization……", an additional reference would include Wydeven et al. 1995.

P. 5, 2nd para. the following statement is not totally accurate, "Fuller (1995) suggested that clusters of 2-3 packs (area of 200 square miles) represents the minimum number of packs necessary to support a viable population". The actual statement in Fuller (1995) was "The smallest demographically viable population not too far from other wolves…. might include two or three adjacent packs of four wolves each ….". This is not the same as saying 2-3 packs form a viable population. The statement needs to be rephrased.

P. 5, this section on habitat should also include other reference on potential wolf range in WI such as Smith at al. 2016 (Supplement to main paper) estimates 55,059 km^2 (21,258 mi^2) of suitable wolf habitat in Wisconsin, and Gantchoff et al. 2022 estimate 27,757 km^2 (10,719 mi^2) area of most suitable wolf habitat in winter. Also, you may want to cite ven den Bosch et al. 2022, as additional reference on wolf habitat in WI, and how the areas of wolf habitat are well connected across MI and MN, and adjacent areas of Canada, but poorly connected to other areas of potential wolf habitat across the US. This section could also use a reference to Stenglein et al. (2015b) that 1242 wolves are the most recent estimate of the potentially biological wolf carrying capacity for WI.

P. 5, last para., it might be better to report at least 256 packs detected in Wisconsin in 2020. The estimates of packs by scaled occupancy modeling, unlike overall wolf count, has not overlapped with minimum counts on packs in the state. Thus, it remains unclear on the ability of SOM to be able to accurately estimate packs, and might be best to use a recent minimum count of wolf packs. The 256 packs were the highest number of packs ever detected by direct counts in the state, and at a time the

WIGreenFire.org
PO Box 1206, Rhinelander, Wisconsin 54501 | Info@WIGreenFire.org

population was the highest number ever estimated by either minimum count or SOM. It seems highly unlikely with decline in wolf numbers in 2021 and 2022, that pack numbers would have continued to increase.

P. 5, last para. includes discussion on current wolf range in WI. It may be more accurate to say, "…. overall wolf range has grown to as much as 73,796km^2 (28,493 mi^2), of which 55,219 km^2 (21,320 mi^2) had a >40% probability of being occupied by wolf packs. Thus, likely occupied wolf range is similar to estimates made by Smith et al. 2016 and is somewhat high than described by Mladenoff et al. 2009."

P. 10, the following seems incorrect, "Lone wolves, often dispersing wolves, are considered to be their own pack until they join." I assume this was intended to be "are considered to be on their own until they join….".

P. 11, under "Reproduction" should clearly state that "multiple litters" are 'from additional breeders in the pack' and not the same pair.

P. 12, section on dispersal lists Callan (2013) as a reference on dispersal. It is not listed in LITERATURE CITED, but the article Callan et al. (2013) is an examination of trophic cascade, not about dispersal. Treves et al. (2009) would be a better reference here.

P. 12 may want to include a statement that apex predators are normally controlled by members of their own species, other apex predators, prey base, or humans.

P. 13, on trophic cascade, it would be good to include Gaynor et al. (2019) on human disturbance interacting with predator impacts.

P.13-15, under discussion of trophic cascade, you may want to include Sinclair and Krebs (2001) that trophic relationships are complex, and the effects are non-linear; sometimes being top-down, other times bottom up, and often a mixture of both.

P. 13, Callan et al. 2013, & Mech et al. 2012 are missing from LITERATURE CITATIONS

P. 14, Bouchard et al. 2013 is cited in 2nd para. under "The 'Landscape of Fear' and Ecosystem Effects". This citation is missing from the LITERATURE CITATIONS.

p. 14, "Wild Canines" should probably be "Wild Canids."

P. 14, in last par. "Crimmins et al. 2019" should be "Crimmins and Van Deelen 2019".

While Crimmins & Van Deelen (2019) did not detect wolf impact on coyote distribution at the scale of 10-mile snow-track surveys in Wisconsin, Levi and Wilmers (2012) did find difference between wolf and coyote distribution using scent post surveys set a at 0.3-mile intervals along 2.7-mile transects in Minnesota. Different scales or different wolf densities might be factors between the sites. Newsome and Ripple (2015) found that on a continental wide basis, displacement of coyotes by wolves was not distinct until 200 km (120 miles) into wolf range. Because wolves have more recently colonized Wisconsin compared to Minnesota, and most wolves in Wisconsin are less than 120 miles from the edge of wolf range, they would less likely be impacting coyote distribution. Though research such as Flagel et

WIGreenFire.org
PO Box 1206, Rhinelander, Wisconsin 54501 | Info@WIGreenFire.org

al. 2017 and Chandler et al. 2020 demonstrate that on localized basis, wolves may be impacting coyotes' distribution and allow for greater presence of foxes.

P. 15 Chandler et al. 2020 is cited but missing from LITERATURE CITED

P. 15, section on "Wolves and Black Bear" should include reference to Ballard et al. (2003) that includes 9 cases of wolves killing black bear (p.264). You also may want to reference 2 cases of black bears killing wolves including an adult female at a den in Ontario (Pimlott et al. 1969, p. 62-63), and killing a wolf pup in the same area (Mills et al. 2008). Mortalities on young wolf pups are rarely detected and bears may be an occasional mortality factor.

P. 15, discussion of bear baits should cite Bump et al. (2013) and include that wolf use of bear baits can exacerbate wolf-hunting dog conflict.

P. 17, the sentence at top of the page seems to be rather dismissive of the potential impact by wolves on CWD, while the prior discussion seems to show good evidence of potential impact. Perhaps a fairer statement would be "While evidence from modeling, information on selectivity by other predators, and lack of CWD spread in areas of wolf pack occupancy, demonstrates potential for wolves to control or limit spread of CWD, additional research is necessary to more definitively demonstrate the ability of wolves to limit the spread of this disease".

P. 18, section on deer survival study in Sawyer County should cite actual papers such as Norton et al. (2021, JWM 85:1232-1242), Olson et al. (2021, Can. J. Zool. 99:912-920), Walsh et al. (2017, Ecol & Evol. 8:509-520), Warbington et al. (2017, JWM 81:824-833), Norton et al. (2016, JWM 80:1323-1331)

P. 18, the title "Prey Regulates Wolf Populations", takes sides on a contested wolf ecological relationship. It would be more appropriate to title as "Regulations of Wolf Populations". Several papers below, as well as continuing research, suggests that this issue is more complex than just prey regulating wolf populations. Evidence is continuing to mount that social factors through territoriality and negative density dependence regulate wolf populations in many places.

P. 18 section on wolf population dynamics under "prey regulates...", Fuller et al. (2003) would be a more correct and specific citation but should also cite papers that imply social factors may regulate wolf abundance below limits set by the prey base (Mech 1970, Van Ballenberghe et al. 1975, Cariappa et al. 2011, Cubaynes et al. 2014, Cassidy et al. 2015, O'Neil et al. 2017, 2020, Smith et al. 2020).

P. 19 under "Human-Caused Mortality", you may want to cite portions of Stenglein et al. (2015b), even though it is mentioned later in the report. Stenglein et al. (2015b) indicates that long-term harvest of30% across the wolf population would lead to declines and possible extinction. But Stenglein et al. (2015b) also demonstrates that varied harvests of 5-20% in primary wolf range and harvests of 75% in marginal areas could lead to stable population of about 1000 wolves. Thus Stenglein et al. (2015b) demonstrates that conservative harvests in core wolf areas and more liberal harvest in marginal areas could lead to a stable population.

WIGreenFire.org
PO Box 1206, Rhinelander, Wisconsin 54501 | Info@WIGreenFire.org

P. 19, also under "Human-Caused Mortality" you may want to cite Hill et al. (2022). Hill et al. (2022) conducted a meta-analysis of 21 wolf studies monitoring fates of 3564 wolves and determined that human-caused mortality accounted for 61% of all mortality. They determined that rates of lethal removals for depredation control were lower in wolf populations that were hunted. Hills et al. 2022 did not detect lower illegal kill rates in hunted populations, but proportion of human-caused mortality was lower in hunted populations, and rates of illegal kills increased in areas with more fragmented natural habitat. Stenglein et al. (2018) also determined that rates of human-caused mortality and illegal kills were higher at the edge of wolf range.

P. 20, Impact of Regulated Harvest, may want to include, "In some situations wolf harvest may impact the ability to enjoy and observe wolves in protective areas (Borg et al. 2016). Mech (2021) has recommended creation of wolf sanctuary areas in large blocks of public forest and around Indian reservations to minimize impact of harvest in such areas." These papers may also be useful for the justification of buffer areas around Indian reservations in Wisconsin later in this report.

P. 20. Harvest and other forms of human-caused mortality can also reduce pack size, pack persistence, and reproduction/recruitment (Ausband et al. 2015, 2017, Cassidy et al. 2023).

P. 20, another potential impact of harvest or human-caused mortality can include greater risk of wolf hybridization with dogs as has been detected in Italy (Santostasi et al. 2021).

P. 20, citations by Bassing et al. 2018 and Bassing et al. 2020 are missing from the LITERATURE CITATIONS.

p. 21. For third paragraph, may want to include this statement at the end. "Stenglein et al. (2015b) did determine that a mix of conservative harvests in core wolf range and liberal harvest in marginal wolf areas did allow for sustainable population of about 1000 wolves."

P. 21, you may want to include a statement about harvest impact on wolf depredations. "Although controls directly at depredation sites are generally the most effective means for reducing wolf depredations, several studies have shown that wolf harvests can reduce depredations or reduce wolves removed at depredations sites (Stenglein et al. 2015b, DeCesare et al. 2018, Hill et al. 2022). During the 3 years wolves were harvested between 2012 and 2014, numbers of farms with depredations declined drastically (Fig.22). Similar results have been observed in Montana (DeCesare et al. 2018)."

P. 22-23, the introduction on human dimensions, could reference Schanning 2009, who provides a good historical background on human dimensions research in relationship to wolf recovery in Wisconsin and the Great Lakes Region. You may also want to reference Shelley et al. 2011 on some Native American attitudes toward wolves in Wisconsin.

P. 27-28, the section on "Common Ground and Management", is somewhat one-sided and misleading. Chapron & Treves (2016) is cited as evidence that authority for lethal controls will not reduce illegal kills but fail to cite 3 separate analyses that refutes that publication (Olson et al. 2017, Pepin et al. 2017, Stein 2017). Also, the publication by Olson et al. (2015), showing reduced illegal kill when the state had authority to use lethal controls, was not cited. Recently additional research in

WIGreenFire.org
PO Box 1206, Rhinelander, Wisconsin 54501 | Info@WIGreenFire.org

Sweden (Liberg et al. 2020) demonstrated that legal culling resulted in reduced rates of poaching. Apparently under some circumstances, authority for lethal controls can result in reduced rates of illegal killing. In a recent meta-analysis of 21 wolf studies, Hill et al. (2022) did not detect reduced illegal killing with public harvest but found illegal kill rates increase with reduced natural cover. The paper by Santiago-Avila et al. (2020) is biased to assumption that nearly all collar disappearance is due to illegal killing and not from any direct measures of illegal kill rates. Unfortunately, there has not been a comprehensive analysis of illegal kill rates since 2012 when the first legal harvests occurred in Wisconsin.

P. 28 along with statement about Hogberg et al. 2016, may also want to quote, Richardson (2022) with evidence of greater tolerance toward wolves after 10 years of wolf hunting.

There is also somewhat of dismissal of effectiveness of lethal controls in this section. While there continues to be disagreement on effectiveness on lethal vs non-lethal control, there are papers that show support for effectiveness of lethal control through simulation modeling at livestock depredation sites (Haight et al. 2002, Stenglein et al. 2015b). Careful examination of depredation management programs in the field have also shown support of lethal management (Harper et al. 2008, Bradley et al. 2015, Poudyal et al. 2016, Kompaniyets et al. 2017). Direct reactive approaches at depredation sites are generally most effective at addressing depredations but regulated harvests also can contribute to reduced depredations (Haight et al. 2002, Stenglein et al. 2015b, DeCesare et al. 2018, Hill et al. 2022). WI DNR and USDA-WS in WI have done extensive work with non-lethal controls on wolves, especially 2015-2020. While this effort has stabilized levels of livestock depredations, they have not been able to reduce levels of depredations as extensively as was seen between 2012 and 2014, when the state had the most flexible levels of depredation management including lethal controls at depredation sites, and public wolf harvest. Similar declines in depredations were observed in Idaho and Montana when flexible state management was available. Using an integrated approach of an array of lethal and nonlethal tools will continue to be the most effective way to deal with wolf depredation on livestock. You may want to cite some of these other articles to give a more complete picture of potential controls using lethal methods.

P. 30, bottom of page. It lists state wolf count of 660 wolves in 2014 when the public attitude survey was conducted. While it is correct that was the population while the attitude survey was being conducted, but that wolf population information was not published until after the public attitude survey. Thus, the most recent estimate of the wolf population was 809 counted the previous winter. If people filling out the survey would have been aware of the latest wolf count, this would have been the number that was last published by DNR prior to the attitude survey.

P. 31 it states that Bayfield County is considered a metropolitan area. That apparently was intended to be Douglas County.

P. 46, 2nd para., along with early reintroduction attempt in 1974 (Weise et al. 1975), a recent reintroduction has again occurred in the Great Lakes region on Isle Royale to re-establish a genetically diverse wolf population on the island (Harvey et al. 2021).

WIGreenFire.org
PO Box 1206, Rhinelander, Wisconsin 54501 | Info@WIGreenFire.org

P. 46, Could include "Wydeven et al. 1995" as reference for early wolf colonization.

P. 50, Figure 16. It would be useful and informative to include occupancy modeling (OM) results for 2018 and 2019 in this figure. A lot of distrust and confusion exist on the new OM population estimations. It would be extremely useful to show the 3 years of overlap between 2 methods, as well as demonstrating that minimum counts fell within the 95% CI of OM during all 3 years. It also shows that the new method was gradually phased in, instead of sudden change in one year. It would also be useful to include the 2022 numbers so readers can better interpret the impact of the February 2021 wolf hunt on the wolf population.

P. 51 the statement in the last paragraph is incorrect, " …annually, 9.4% of all mortality was due to illegal kill…….". This is not percent of all mortality, but percent illegal kill of the population. Overall mortality rate averaged 24%, thus illegal kill of all mortality would be 9.4/24 or 39% of all mortality.

P. 51, Stenglein et al. 2018 is not included in CITED LITERATURE

P. 54, after Cariappa et al. 2011, can also list, Cubaynes et al. 2014, Cassidy et a. 2015, O' Neal et al. 2017, 2019, Smith et al. 2020.

P. 61, near top should include term "shall" in reference to wolf hunting and trapping season to make it clear the WDNR does not have any discretion whether to hold a harvest season.

P. 61, 1st para. May want to modify "use of dogs beginning with first Monday that follows the last day of the regular season that is open to hunting deer with firearms…" to "use of dogs beginning with first Monday after the firearms deer season (first Monday after Thanksgiving) …". This might be easier for non-hunters or people from other states to understand.

P. 62-63 provides useful information on historical funding of the wolf program, but it would be useful here to also show a proposed budget for future wolf management and research work. Projected budgets for the next 5-10 years would be meaningful and can be helpful in attempting to secure funds from cooperators and collaborators.

P. 65, 8th para about end of howl surveys may want to add that howl surveys continue to be conducted in portions of Wisconsin by volunteer efforts with Timber Wolf Alliance and Timber Wolf Information Network in cooperation with Northland College (Shively et al. 2021).

P. 66, wolf depredation investigations can be another source on wolf presence and abundance that could be listed.

P. 68, table 11. Column for "% Human Caused Mortality ", should be "Ratio of Human Caused Mortality" The text that refers to Table 11, should perhaps include a statement that "population growth", is calculated by comparison of Winter Counts from one year to the next. Some members of WGF have recommended using lambda" λ "to show population change, though population growth or decline may be easier for general audiences.

WIGreenFire.org
PO Box 1206, Rhinelander, Wisconsin 54501 | Info@WIGreenFire.org

Also in table 11, the column for "Number killed by humans", should perhaps be "Detected Number killed by Humans", because not all vehicle collisions and most illegal kills would not have been detected.

Table 11 could also be extended to 2022, and convert OM modes to estimates of minimum counts, assuming the minimum count would be ~ 14.5% less than OM mode estimates, and thus 2020-2021 would be ~963, and 2021-2022 would be ~831, Population Growth for the 2 periods would be -0.07 and -0.14 respectively. Such an extended table would demonstrate that population declines occurred even when wolves were not harvest (2017-2018, & 2020-2021), as well as demonstrating decline from 2021 harvest in 2022 (-0.14), but less than decline from harvest in 2013 that lead to decline of -0.18.

Table 11 has the title at the top, while other tables mostly have titles at the bottom, though having the title at the top is general preferred for tables.

P. 70, discussion on origin of 6 harvest zones could include mention that the 6 harvest zones were modified from the original 4 management goals from the 1999 wolf plan (WDNR 1999).

P. 72, the table should mention that counts in 2012, 2013, and 2014 represented minimum counts from previous winter, while 2021 model estimate was just prior to the February 2021 harvest. You might want to use an estimate of the minimum count for 2021 (1,126 -14.5% =963 wolves) with footnote at bottom of table to explain how count was obtained.

P. 73, last para. prior to last sentence you may want to include something like, "Also when state managed, landowner meeting certain criteria can be issued permits to shoot wolves on their land if they or an adjacent landowner have had a history of wolf conflict on their land."

P. 74, for final report it would be good to extend figures 21 and 22 to 2022. The number of farms with depredations in 2021 was probably an outlier in Figure 22. It would also be useful to show a figure of verified cattle killed, which tends to be fairly representative of the overall level of livestock depredation.

P. 74 may want to include, "Most wolf depredations on livestock occur more at the edge of wolf range, and in more marginal wolf habitat (Treves et al. 2004, 2011, Olson et al. 2019). Areas of concentrated wolf-livestock depredations occur in a 600 square mile area of the Lake Superior Lowlands of northwestern Wisconsin and 700 square mile area of the Central Plains just northeast of the Central Forest (Fig. 38, p. 110). These areas have high interspersion of forest, agricultural and/or pasture land and have little or patchy public lands (Olson et al. 2019, Figures 36, 37 and 38 on pages 109-110)." [area estimates are rough from Google Earth, and you may want to refine]

P. 77 may want to cite some examples on nonlethal controls such as Gehring et al. 2006, and Shivik 2014.

P. 79, at bottom of page could reference to wolf conflicts at bear baits to Bump et a. 2013.

P. 80, an additional paper to cite on landscape predictors of wolf attacks on hunting dogs would include Olson et al. (2014). Olson et al. 2014 demonstrate that core areas of wolf habitat (Mladenoff et al. 2009), are the most frequent location of such depredations, while livestock depredations occur more frequently in marginal wolf habitat (Olson et al. 2015a, 2019, Treves et al. 2004, 2011)

WIGreenFire.org
PO Box 1206, Rhinelander, Wisconsin 54501 | Info@WIGreenFire.org

P. 81, 2nd para. may want to include the 4-mile radius would cover a 50 square mile area, close to the average historical size of a wolf pack territory. Also, should mention caution areas are created in part because often when a dog depredation begins to occur within a pack area, frequently the pack will continue to attack dogs during the same season, and hunters will want to try to avoid specific locations where depredations occurred.

P. 81-83, Linnell is misspelled.

P. 82, End of last para., may want to include "Occurrence of human safety concerns seemed to have peaked between 2010-2015, but have declined in recent years."

p. 84, in last para., Boitani 2003 is not in LITERATURE CITED.

p. 84, in last para, some additional publications to cite could include Haight et al. 2002, Fritts et al. (2003 p. 310), Harper et al. (2008), Bradley et al. (2015), Stenglein et al. (2015), and DeCesare et al. (2018). May want to add here as well that while wolf harvests have some potential for reducing depredation on livestock, the type of harvested conducted in Wisconsin in February 2021 mostly occurred on wildlands away from areas with livestock-wolf conflicts (Wydeven et al. 2021, p. 10).

P. 85, last para. may want to add this to the end, "In research on Mexican wolves in Arizona, producers were able to detect one of every 3 missing calves in one location, but nearly 4 of every 5 missing calf in a second location (Breck et al. 2011). Apparently, ability to detect predator kills on livestock, varies greatly across different landscapes. "

P. 86, section on "Publications", can include the following, "The department periodically joined with other organizations to produce guidelines such as National Wildlife Federation et al. (2003) pamphlet on 'wolves hunting dogs', and National Wildlife Federation (2005) fact sheet on 'wolves and deer'. The department also help sponsor, produce, and distribute posters for Wolf Awareness Week from 1990-2012. These posters typical featured accurate depictions of wolves in natural habitat, and the back of the posters provided updated information about wolves across the US, and featured events and research important to wolf conservation. These posters would be made available for free distribution to the public from regional and local DNR offices across the state".

P. 90. 1st par. May want to include after "…Wolf Awareness Week in Wisconsin", 'and across the US and North America since 1990. Education posters are made available across the US and are distributed through libraries nature centers, state parks, DNR offices, and Forest Services offices across the state."

P. 91, after 2nd para. may want to include information from Brandell et al. (2021). Possible example could include, " Recently Brandell et al. 2021) surveyed wolves from 17 study areas across North America for four viruses (adenovirus, herpesvirus, parvovirus, and distemper), and two protozoan parasites (*Neospora caninum* and *Toxoplasma gonii*), and found seroprevalence increased with age, wolf density and areas of higher human density. *Neospora caninum* was most prevalent in wolves from the Great Lakes region, possibly because white-tailed deer consumed by wolves are considered an important reservoir for the parasites (Brandell et al. 2021)."

WIGreenFire.org
PO Box 1206, Rhinelander, Wisconsin 54501 | Info@WIGreenFire.org

P. 97. Justifications for changing from a numeric goal (target population goal), to responding to ecological conditions goal, is useful, but might seem less defensive if the first and second paragraphs are switched around, along with some slight modification of introductory sentences. Some of the arguments against numeric goals could include, changing understanding of suitable wolf habitat (Mladenoff et al. 1995 vs. 2009), changing understanding of biological carrying capacity or potential populations (Mladenoff et al. 1997, Van Deelen 2009, Stenglein et al. 2015b), and changing attitudes and public acceptance of wolves (Schanning 2009, Holsman et al. 2014, Bradshaw et al. 2022). As ecological conditions vary and public attitudes vary, numeric goals become arbitrary over time. Also, many who would like to see wolves reduced to much lower numeric goals, also distrust DNR wolf population surveys, and would not still likely be satisfied if numeric goal were achieved.

P.97, In discussion of wolf management, it should be mentioned again that under ACT169 the DNR is required to annually hold a wolf hunting and trapping season, anytime gray wolves are not on the federal or state endangered or species list. Additional ACT169 restricts and limits the DNRs ability to modify portions of the hunting and trapping regulations on wolves such as start of season, potential end of season if quotas are not achieved, limits DNR ability to modify methods of take, prohibits DNR from closing portions of Wisconsin to wolf harvests, and limits other aspects of managing the state wolf harvest. It needs to be clearly stated that ACT169 places sideboards on how the DNR manages wolf harvest in Wisconsin that differs from the adjacent states of Minnesota and Michigan.

P. 97, end of 2nd para., Fuller et al. (2020) is not listed in LITERATURE CITED.

P. 99, the Plan Goal should include timeframe over which the plan is being considered such as 2023-2033, and frequency of plan review.

p. 102, Table 13 of objectives and metrics. Some members of WGF have questioned whether the table identifies metrics vs strategies. The table should perhaps refer to pp. 111-139 where more specific metrics are listed for each objective.

P. 102, under "Objective E" 2nd bullet could include "Tribes" on collaborations. Several tribes are involved in research and active monitoring of the wolf population.

P. 102, under "Objective E", could include a bullet of "strengthening opportunities for citizen scientists' involvement in wolf monitoring and research.

P. 103, Fig. 34, map of proposed zones, in general looks very good, but western Lincoln County probably should have been kept in Zone 1 or 2. This was one of the original two counties with wolf packs when DNR started monitoring in 1979 (Wydeven et al. 1995). The area has always tested as highly suitable wolf habitat (Mladenoff et al. 2009). The area also has not experienced livestock depredation in recent years (Fig. 38, p. 110). I recommend using Co. D, WI/102, WI/86, and Co. C as western boundary and add to zone 1 across US 8 to the north.

P. 104-105, tribal lands listed as "zero quota" areas is repeated in two places, and probably only needs a single mention.

WIGreenFire.org
PO Box 1206, Rhinelander, Wisconsin 54501 | Info@WIGreenFire.org

P. 105-107, important metrics for assessing wolf population health and viability, and fulfilling ecological functions, would include average population, density, average pack size, pack integrity, dispersals among zones (Rick et al. 2017), livestock depredations, pet depredations, human safety issues and spread of diseases such as CWD. In core wolf areas zones 1, 2 and 5, and subzones 1b and 2b, management should attempt to maintain average packs size and population density at levels similar to what have been observed in unharvested populations the last 10-15 years. Average pack size may be a good index for ecologically functioning population in that larger or moderate pack size are more successful in raising pups, maintaining territories, and efficiently catching prey. CWD has not spread much into areas with healthy wolf packs in Wisconsin and should be carefully monitored especially any positive samples near or in areas occupied by wolf packs. In general harvest management in zones 1, 2 and 5 should maintain wolf populations and densities near current levels. In zones 3, and 4 major reductions should be avoided in wolf population, density, or average pack size, especially near areas where CWD has been detected. Any CWD outbreak in or near wolf ranges should be carefully monitored, and research should be conducted to determine degree wolves are able to select infected deer. Genetic monitoring such as Rick et al. (2017) should be used to determine whether portions of the wolf population are becoming isolated and examine whether healthy levels of genetic interchange continue, especially in Indian reservations and for Zone 5.

P. 111, Under "A1a" could include, the following, " …. field observation reports of dead wolves, mandatory harvest registration, collection of biological samples from harvested wolves when necessary, and mandatory reporting of control mortalities."

P. 112 may want to include category supporting collection of data on local wolf population abundance being done by tribes, Timber Wolf Alliance, Timber Wolf information Network, Northland College, or other college or universities that are helping collect auxiliary information on the wolf populations.

P. 113, statement on use of occupancy model, implies that it started in 2020. Seems like it was really started in 2018. It would be useful to show that both methods were used in a gradual phase in and was not just a sudden change.

P. 117, B1b, under 'depredations guidelines', these have been done since 2002, and periodically updated, with most recent version approved in 2014.

P. 123, the opening defining sentence should include a statement to also encourage inclusion of Indigenous values in wolf conservation.

P. 123, discusses zone-specific population objectives of increase, decrease, or maintain wolf population. This needs to be set in time frame; will be this be done annually for each zone and subzones?

P. 125-127, We strongly support zone specific permits, with the provision that subzone permits can be used in either main or subzone area. It may be useful as well to issue permits specifically for public or private land to focus greater controls in areas of conflict. We also strongly support harvest registration within 8 hours. We do have some concerns about keeping harvest permit numbers too low and causing seasons to last for many months. Closures by late November or early December would be preferable to avoid having harvest activity disrupting winter track surveys, or to disturb wolf breeding activity in late

WIGreenFire.org
PO Box 1206, Rhinelander, Wisconsin 54501 | Info@WIGreenFire.org

January and February. There is a trade-off between providing maximum recreational opportunities and causing disruption of tracks surveys and creating major disturbance for wolf packs. The longer the season, the greater the disturbance level for wolf packs. The types of seasons held in 2012-2014, with all zones closing by early or mid-December seemed adequate for providing reasonable hunting and trapping opportunities, ability for DNR to control harvest, while minimize disruption of surveys, or disruption of wolf packs and breeding activity.

P. 127, we appreciate attempts under C2h to create opportunity through administrative rules to establish a regular training period for dogs used to hunt wolves but have great concern keeping such a season open until the end of the last zone is closed. In the past, zone 6 remained open long after all other zones were closed, and with reduced area of wolf habitat in proposed zone system, this zone could remain open well into the winter period. Bobcat hunting in December and January already are somewhat disruptive to winter tracks survey activity, and addition of more hound running activity would likely further disrupt track surveys. Such hound training activity into mid-winter is likely to be disruptive to wolf territory maintenance and breeding activity. We strongly recommend that zones only remain open to dog training while the zone is open to regular hunting and trapping activity.

P. 127, under C3a, the department does not identify any way it will be promoting non-consumptive recreation. You may want to include that "groups such as Timber Wolf Alliance, Timber Wolf Information Network, Wisconsin Natural Resources Foundation, as well as some local nature centers sponsor wolf howling events to allow members of the public to hear wolves and explore areas of wolf range in the state. The Department will continue to encourage and monitor such activities, to ensure that such activities do not disrupt local wolf packs or interfere with other recreational activities." You might also discuss volunteer opportunities to track and study wolves in the wild through DNR Carnivore Tracking program, and workshops sponsored by TWA, TWIN and others.

P. 129, mislabeled as p.140 at bottom of page.

P. 129-131, Objective D on public education, some WGF members are concerned that recent cuts in communications may limit the ability of the DNR to address education concerns. The recent public attitude survey indicates that there continue to be great needs for public education.

P. 129, Product D1c, ensure wolf plan is widely available, may want to create a general summary report for broad public use, perhaps as a supplement to the DNR Natural Resource Magazine.

P.131, Product D3b, under collaborators, may want to include science teachers and organizations such as Wisconsin Society of Science Teachers. Such groups can help develop lesson plans about wolves for students that align with Wisconsin Science Standards where students figure our explanations for phenomena and make sense of the world. DNR wolf education efforts should support DPI missions related to science.

P. 132-135, under research may want to include updating Integrated Population Modeling (IPM) like the work of Stenglein et al. (2015b). Such research could be done in DNR or by college/university collaborators. IPM should be used to compare to Occupancy Modeling, which could include,

WIGreenFire.org
PO Box 1206, Rhinelander, Wisconsin 54501 | Info@WIGreenFire.org

incorporating estimates of poaching, effects of pack disruption, dispersal from core areas to marginal areas, reduced reproduction or stability in smaller packs, and other factors.

p. 132, under strategy E1, may want to include a section on supporting auxiliary studies on sub-sets of the wolf population by tribes, universities, colleges, and volunteer organizations including minimum counts on packs within specific study areas, howl surveys, population dynamics, ecology, and other wolf population surveys and monitoring activities.

P. 134, under strategy E5, may want to include updating information on illegal kill rates and how it varies under varying management authority, spatial and temporal changes, and contributing factors. No extensive research has been done on Wisconsin wolves since hunting seasons occurred in 2012.

P. 134, under strategy E5, may also want to conduct research into Traditional Ecological Knowledge (Moller et al. 2004) among Tribes in Wisconsin, and examine how such knowledge compares and contrasts with conventional resource management under the North American model of wildlife conservation (Serfass et al. 2018).

P. 134-135, conduct research on potential of wolves to impact on spread of Chronic Wasting Disease. In areas where CWD has been detected within or close to wolf range, attempt to survey wolf killed deer for infection, and compare to infection rates of general harvest and vehicle collisions.

P. 136, mislabeled as p. 140 at bottom of page.

P. 137, under "Stakeholder Group Definitions" could also include,

- Wildlife/Conservation science organizations: Organizations whose mission includes protecting wildlife and habitat through scientific and thoughtful management; specifically promoting the use of the best available wildlife/conservation science and management techniques.

P. 138, under strategy F2a, should include study of management outcomes as perceived through Traditional Ecological Knowledge (Moller et al. 2004), and conventional wildlife science, jointed funded by WDNR and GLIFWC.

P.140-157 Literature Cited, missing citations are listed above. When likely citations were known, they are listed below under LITERATURE CITED, but not all detected missing citations are listed.

P. 142, Carbyn and Paquet 2003, should be Paquet and Carbyn 2003.

P. 150, Wydeven et al. (2009) is incorrectly shown on this page. There are 2 versions of Wydeven et al. 2009 shown in Literature Cited. They should be listed as 2009a or 2009b, but possible the version on p. 150 is not necessary for the report.

P. 158, we recommend adding western Lincoln County to zone 1, by creating a western boundary of Highways Co. D, WI 86, WI 102, & Co. C. The eastern boundary of US Highway, and south boundary of US 64 would continue, but north boundary of US. 8 should remain.

P. 159, include area of subzone in square miles.

WIGreenFire.org
PO Box 1206, Rhinelander, Wisconsin 54501 | Info@WIGreenFire.org

P. 160, include area of subzone in square miles.

P. 161, include area of subzone in square miles.

P. 162, include area of subzone in square miles.

P. 163, include area of subzone in square miles.

P. 164, include area of subzone in square miles.

P. 165, include area of subzone in square miles.

Sarah Barry
Deputy Secretary
Wisconsin Dept. of Natural Resources
101 S. Webster St.
Madison, WI 53707-7921

Dear Deputy Secretary Barry,

At our Board meeting today, the Wisconsin Wildlife Federation, with more than 211 affiliated grassroots hunting, angling, and sporting conservation clubs and alliances throughout the state, approved the following response to the WDNR 2022 Draft Wolf Management Plan and requests the Wisconsin Department of Natural Resources take the necessary actions to address the following points in a revised draft or final plan:

Public Comment:

1. The current 60-day public comment period in not an adequate amount of time to gather input considering the timing of the release overlaps with hunting seasons and multiple holidays. We request the timeline be extended to 90-days.
2. Not all residents have email or computer access in their homes. For this reason, we request the WI DNR provide multiple and widely distributed announcements of opportunities and methods for public input along with comment period deadlines.
3. There is no means for submitting additional supporting information to the WI DNR for consideration in the draft plan. The Wisconsin Wildlife Federation requests the WI DNR provide the public with an email and mailing address to submit comments and additional supporting information.
4. The Wisconsin Wildlife Federation strongly requests the WI DNR hold public hearings across the state and hold more in wolf affected zones for input on the draft plan.

Inclusion/Exclusion:

5. There is no provision for the inclusion of comments from county and local governments into the draft plan. Many county and local governments have taken positions on wolf population goals and must be included in the process.
6. A functional advisory committee with a balanced mix of impacted stakeholders would vastly improve this ongoing process.

Public Survey Methodology:

7. The public survey does not adequately represent those actively impacted by wolves. Use of county and zip codes to select samples does not accurately reflect those exposed to wolves and impacted by wolves. We request the WI DNR actively seek out those impacted by wolves and place greater emphasis on their perspective.
8. Survey design is flawed. Survey length discourages responses from some individuals. Terminology is undefined and could be seen as biased. Some questions lack balance in positive and negative responses, causing an imbalance in responses. All these features of the survey alienate some individuals causing them to not respond.

Population Estimates:

9. Approximately 40% of the wolf tracking units are not tracked to the required three-time standard and not all units are tracked. This lends itself to under-counting and under-reporting wolf population in those wolf tracking units.

10. Lone and dispersing wolves are not counted in the current population model as is done in western states. Some states add 12% or 15% to their estimates to account for lone and dispersing wolves. We urge lone wolves be included in Wisconsin's population estimate.
11. The WI DNR is not taking full advantage of public reporting of wolf sightings. The online tool for reporting should be better advertised and the WI DNR should clarify that personal information is protected and not available as public record.
12. GPS collar tracking provides the WI DNR with useful information on travel patterns and pack locations for counting. Increased use of GPS collars should be considered.

Conflict Management:

13. The draft management plan is passive and lacks active conflict management for depredations of non-agricultural domestic animals such as dogs and other pets. Increased harvest is not a method identified in the draft plan to reduce such depredations. Include targeted population reduction in areas of heavy depredation of dogs and other non-agricultural domestic animals. This should include all legal methods of harvest for targeted population reductions.
14. The draft plan does not address a numeric conflict reduction goal. We request a goal be set and included in the plan so effectiveness of methods can be measured.
15. The draft plan appears to have biases against hunting with dogs. Hunting with hounds has the same statutory and state constitutional protections as agriculture and should have equal active measures preventing depredations.
16. We oppose the plan wording encouraging low road densities in large tracts of public lands, which is another means to prevent hunting, fishing, trapping, and other public land use opportunities.
17. We oppose the plan wording that implies hunting conflicts are the fault of the hunter. The draft plan needs to address using population management of wolves as a method to reduce hunting conflicts. Hunters have Constitutional rights to hunt lands open to them despite the presence of wolves.
18. Currently there are multiple systems for sending alerts for livestock, hunting dogs, and non-agricultural animals, but the plan is missing human health and safety alerts. Receiving the same notification with a 4-mile radius map is necessary to help prevent potential conflicts for land users, pet owners, and dog hunters around those areas. We request the WI DNR provide equal notifications for equal protections for all land users.
19. Those who have personally experienced conflicts with wolves may have traumatic experiences and stresses. The psychological impacts on humans caused by livestock and domestic depredations by wolves is real and needs to be considered. The draft plan ignores the psychological impacts wolf conflicts have on humans and this needs to be addressed in the plan.

Zone Changes:

20. The plan includes the creation of buffer zones surrounding reservations, effectively giving the management of the wolf population on both public and private lands to the tribes. We oppose the creation of buffer zones surrounding reservations that would take away the rights of private landowners and public land stakeholders. We also oppose giving away wildlife management authority.
21. The agricultural areas in these newly created buffer zones in the draft plan will go largely unprotected and have inadequate protections for pets and livestock. Private landowners will have unequal treatment under the law for which they are protected under the Constitution.
22. The zone restructure is now based on wolf occupancy and not based on suitable habitat. The unmanaged wolf population has forced wolves out of prime suitable habitat into inappropriate areas, creating conflicts. Not all areas are appropriate to have wolves. We request the zone structure return to the original science-based, habitat-based zones.

Goal Statement/Objectives:

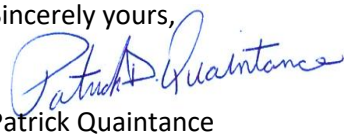
23. The Goal Statement in the draft plan does not address where wolves are appropriate. The draft plan needs to take a hard look into what is good for wolves and what is good for humans. Low interactions between the two are best. Wolves should only reside in high-quality wolf habitat and not be managed to the maximum biological carrying capacity. No other species in Wisconsin is managed to its maximum biological carrying capacity.
24. The draft plan implies the elimination of hunting with dogs which is Constitutionally protected. It also implies wolves have more rights to the land than hunters. This narrative is not science-based and all such implications should be removed.
25. Objective B is missing long-term controls for agricultural conflicts. Wolves are known to move down the road and create conflicts with just short-term controls.

26. The goal statement or objectives do not address any form of population control. The official position of the Wisconsin Wildlife Federation is a population goal of 350 wolves in the State of Wisconsin. We strongly request the numeric population goal of 350 wolves be maintained in the final plan.

Numerical Population Goal:

27. The draft plan allows for a subjective process for managing wolves. The population goal was established in the 1999 plan due to lack of confidence in a subjective wolf management strategy. There is no accountability without a numeric population goal. The only scientific analysis of wolf habitat done to-date of Wisconsin landscape quantified the social carrying capacity as 350 wolves. The Wisconsin Wildlife Federation strongly requests maintaining the numeric population goal of 350 wolves in the final plan.
28. For increased accountability the population goal needs to have a timeline for completion. The goal timeline allows measuring of progress towards meeting the set population goal with milestones along the way. We request a population goal timeline be added to the plan.

Quotas/Permits:



29. The western states have 13 years of harvest data in establishing quotas to reach their wolf population goals. We recommend including this data in the draft plan to aid in establishing quotas.
30. Permit issuing methodology should be based on the likely harvest methods used in the season they will be issued.
31. Western states have been unable to reduce their wolf numbers consistently despite high levels of human take. As wolf expert David Mech said, “Wolves are prolific, disperse long distances, readily recolonize new areas where humans will allow them, and are difficult to control when populations become established."

Delisting:

32. For lethal wolf conflict control and population management to take place federal delisting is required. To-date the Wisconsin Department of Natural Resources has had no visible involvement in planning, researching, and federal delisting efforts with the USFWS or with legal representation in delisting efforts. The Wisconsin Wildlife Federation strongly requests the WI DNR have a strong and visible presence, and active involvement in all federal delisting efforts that impact Wisconsin and in support of all other states actively working towards delisting wolves in their states.

The Wisconsin Wildlife Federation requests the Wisconsin Department of Natural Resources incorporate the above actions and requests for updates into the 2022 Final Wolf Management Plan.

Sincerely yours,

Patrick Quaintance
President

Public Comments on the draft Wolf Management Plan

December 14, 2022

My name is Steve Suchomel representing Wisconsin Wolf Facts and was a member of the committee involved in discussions regarding the Wolf Management Plan.

The draft wolf management plan is not acceptable. In my opinion it is unworkable in implementation.

The proposal does not protect the resource. For a number of reasons that will be elaborated later, this plan does not address this issue in any logical or justifiable scientific manner.

1. The draft proposal does not specify a set population of wolves. Much discussion dating back to the initial wolf plan decades ago had an agreement of 350 wolves which was an increase from initial discussions of 175 wolves. The initial discussions centered on numbers to keep wolves off the endangered species list. We don't need the current wolf population to protect them from endangerment. We need a numeric goal to manage the resource which should be the 350.
2. The draft proposal is a wolf expansion plan. There are many reasons wolves were eliminated from the bulk of Wisconsin. There is a legitimate safety issue for both man and livestock when interaction with an apex predator occurs. The new plan expands zones 1, 2 and 5 into areas that were previously considered secondary habitat, expands zone 3 into previously designated low priority habitat, and dramatically moves zone 4 into areas previously designated as unsuitable wolf habitat. Wolf zones should be based on an analysis of suitable wolf habitat considering biological and social analysis.
3. Human / wolf negative interactions must be kept to a minimum. Public opinion supports this. Public opinion from those people living or interacting with wolves dramatically supports this. Question 47 of the Conservation Congress spring hearings supported this by a 4 to 1 ratio. Between 2010 and 2017, 36 county boards (half of all counties) passed wolf control resolutions favoring a population goal of 350 or less. In 2021- 2022, 16 county boards passed new wolf control resolutions favoring 350 wolves or less and nine counties decided to send in their previously passed resolution.
4. There is no scientific rationale for expansion of the buffer zones.
5. The plan does not address the economic impact of the wolf expansion plan in the expanded areas. Current economic impacts of the present wolf populations should have been addressed. The wolf population has impacted other hunting opportunities significantly – deer, bear, grouse (with dogs) and recreational such as hiking and pets. The draft wolf management plan does hint at the interaction with other species but in very nonspecific "grey" wording.
6. This plan does not protect the quality of wolf life – should you be a wolf. Wolves are a wilderness animal. They deserve large blocks of road less area with no or minimal human populations. With the exception of Federal and / or State forests, northern Wisconsin is predominantly private owned with an existing agricultural presence.
7. This draft wolf management plan is NOT the product of the committee involved. Specific discussion points were completely ignored. It "appears" that a wolf expansion plan was the DNR goal and the committee was a public relations approach to endorse it.
8. There are minimal specific details in the draft as to reimbursement under wolf damage claims. There are minimal scientific references to existing wolf programs in other states.
9. Without proper management tools and wolf population controls, human safety is an issue.

Wisconsin draft Wolf Management Plan comments 27 Feb 2023

Thanks for all the hard work that was put into producing this draft Wolf Management plan. I appreciate that you have taken into account public input, Tribal concerns and incorporated science and education into the plan. Thank you for conducting a survey of public opinion of wolves in Wisconsin. Please continue to do this periodically. I am a farmer and live in central Wisconsin, in what you have listed as Zone 4a. I own 171 acres of mixture of woodland and farmland in this area.

In general, I support the draft plan but I get the feeling it is geared mostly to lethal control measures for dealing with any conflict with wolves on the landscape. I wish there was a lot more emphasis on non-lethal measures used to deal with conflicts, especially dealing with farmers. I do not support the plan of having the greatest harvest goal in Zone 1a and 4a, in which I live. I have never seen wolf evidence where I live. Currently with hunters using dogs to hunt coyotes in this area they do not seem to care that they and their dogs trespass on my land and any neighbor's land where they do not allow hunters. Dogs are not controlled and they are able to run wherever they seem to want to go. Just this past weekend coyote hunters with their dogs ran through the area and the only thing they seemed to be chasing was a herd of about 12 deer. The last 3-5 years I've called the Sheriffs about trespassing hunters and their hounds running through my land. So I have to keep aware of whenever hunting season is and continue to worry about trespassers with their dogs ravaging the landscape and whatever and all animals that are in the area. Also, there are many farmers in the area that have too many deer that eat the field crops. Yet you want to reduce any wolf population in Zone 4a that could help control that population naturally. Why aren't you emphasizing non-lethal controls?

I do agree with many of the items as written which are:

- Doing away with a numeric goal and allowing for a adaptable population. I support the goal of a self-sustaining, self-regulating, and genetically diverse wolf population that maintains connectivity with wolf populations in neighboring states and fulfills their ecological roles.

- Respecting the Tribal rights and lands and creation of the buffer zones and having low limit zones around Tribal lands. I wish they were no kill zones around these Tribal lands. Tribes were here long before us Europeans and have long lived with wolves and treat them differently so we should respect that.

- I'm happy to see based on public surveys that the DNR has acknowledged that most people in the State want a healthy wolf population based on science and have tried to develop a plan reflective of this.

- It briefly mentions and acknowledges that wolves are a keystone species that play a very important role in a healthy ecosystem. This should be emphasized in greater detail and should be researched and collaborated with other experts as mentioned.

- There is a section dealing with public education regarding the importance of wolves and how they are scientifically important and about using non-lethal methods for reducing wolf related conflicts.

- I definitely support the recommendation to changes to the administrative rules that decrease the required time to report wolf kills to not later than 8 hours, and making the destruction of occupied wolf dens illegal, which should never occur regardless of occupied or not.

- Agree with issuing wolf harvesting licenses which are only valid in the specific zone specified on the license, instead of valid in all zones.

- Agree and appreciate the public and farmer educational aspect of this plan. Emphasis on education of non-lethal controls to farmer community should be budgeted for and enhanced.

- Concur with conducting studies on effects hunting with dogs has on the wolf and dog conflicts (product E3c) Maybe the issue of hunting with dogs is the issue. Should this even be allowed based on the scientific research? Maybe all hunting with dogs should be eliminated as wolves are still around when bears, etc are hunted with dogs. This conflict will never be eliminated and maybe dogs should not be used to hunt.

Areas that I do NOT agree with or should be adjusted:

- More emphasis on non-lethal controls for areas that tend to have wolf-related conflicts instead of raising the harvest goal, especially in Zone 1a and 4a. Subsidizing farmers to implement non-lethal controls should be pursued. If there are lethal controls used prior to the legal hunting season these numbers should be included when setting harvest goals as already harvested. Do studies show that disrupting the wolf family structure actually deters conflict? What does science indicate are better ways to deal with these conflicts?

- Put emphasis on wolf viewing and eco-tourism for wolves. Put money or grants into setting this up in the future.

- There is no mention of obtaining State money for implementing non-lethal controls. This plan should lay out plans for State budgeting for non-lethal controls to better reflect what your science is telling you that non-lethal controls work and may be a better deterrent for wolf related conflict than killing.

- There should be no night hunting allowed.

- Do not agree with CITES application. This could lead to extreme trophy hunters and lead to poaching and black market. We don't need to have our Wisconsin wildlife marketed worldwide.

- The plan should review Act 169 and recommend legislative changes based on the science and the parameters of this plan in creating a healthy and sustainable wolf population for an overall healthy ecosystem for Wisconsin. The DNR should be able to better manage any wolf harvest based on the science instead of political interference.

- The DNR should better regulate hound training on wolves. The DNR should close wolf-focused hound training activities as each wolf zone closes, instead of what is recommended in the plan of having state wide training till all zones are closed. This would interfere with breeding season and put dogs at risk.

- There should be permanent, ongoing oversight by a stakeholder group and a science committee to oversee wolf stewardship in Wisconsin. The stakeholder group must be inclusive and recognize the importance of Tribal oversight.

- Wolves should be encouraged in areas that have a CWD issue with the deer herd. Wolves are a better control for this devastating disease than any human control ever good be. If deer are putting pressure on agriculture fields maybe wolf population should be encouraged in that area.

I appreciate the comprehensive plan as presented. Please do not cater to the trophy hunters and stick with the science of wolf management as you progress to the final product. I appreciate the respect you show to the Tribes as they are the true owners of this land and its wildlife and they know better how to manage it than most. I appreciate the emphasis you place on education and hope that you are able to carry this out in the future. Emphasis on non-lethal controls should be made instead of lethal in dealing with wolf related conflicts. I believe science indicates non-lethal works better. I hope this plan can be continued on into the future regardless of who politically is running the State and Legislature. This should be non-partisan.

Thanks for your work,

Joan Arnold

From: Kerry Beheler, Mount Horeb Wisconsin

RE: Review and Recommendations for the Wisconsin Department of Natural Resources draft Wolf Management Plan, released November 2022. Public comments due 28 February 2023.

I. Aspects of the draft Wisconsin Wolf Management Plan to Support: The Wisconsin Department of Natural Resources (WDNR) is commended for the draft Wisconsin (WI) Wolf Management Plan, released in November 2022. I support the following concepts of the Plan:

1. No numeric wolf management population goal
2. Commitment to long-term wolf stewardship
3. Manage to a sustainable statewide population
4. Emphasis of the ecological benefits wolves provide
5. Proposed protective buffer zones around tribal reservations
6. Statewide overall zone-specific harvest permits
7. Commitment to scientific and collaborative research to guide management decisions
8. Commitment to an adaptive management plan

II. Aspects of the draft Wisconsin Wolf Management Plan to Revise or Remove: There are specific concepts and areas of the draft Plan which need revision or removal, listed below.

A. There is a need for separate Wolf Science and Wolf Stakeholder Committees, and public outreach suggestions regarding the draft WI wolf Plan. Wolf management is an area of great attention and concern for tribal nations, government agencies, academic institutions, and many stakeholder groups and individuals. Various suggestions regarding wolf stewardship and management are a consequent result. To avoid controversial, emotional, non-scientific and political influences as much as possible, the WDNR should have separate Science and Stakeholder Advisory Committees. WDNR previously had functional, respected, and separate committees. Recreating a separate Science Committee would strongly indicate WDNR's commitment to science-based wolf stewardship and inclusivity of myriad views. The WI Wolf Science Committee can be organized similar to the Minnesota (MN) Wolf Technical Committee, and include scientists and biologists from multiple disciplines representing Universities, Cooperative Extension, United States Department of Agriculture, United States Fish and Wildlife Service, WDNR, regional Departments of Natural Resources, and others.

Questions and suggestions for WDNR include:

1. Who will be the members of the separate Science and Stakeholders Committees?
2. When will the list of possible participants be available?
3. How often will the Committees meet, regardless of wolves' legal status?
4. I recommend the WDNR hold in-person public hearings in at least 3 different locations across WI after the public comment period has ended on 28 February 2023, and before the WDNR has created the next version of the WI Wolf Management Plan.

5. I recommend the WDNR reconvene the 2021 WI Wolf Advisory Committee to review/revise the next version of the Plan the WDNR will create after all public comments have been added, and before the Plan is finalized.

B. Hound dog training period on wolves as proposed in the draft Plan must be removed or revised. WI is the only state that legalizes the hunting of wolves with dogs. Using trailing hounds for pursuit while hunting, or for training the hounds to pursue wolves, is cruel for both wolves and hounds. This practice is not supported by the majority of ethical hunters or the broader public (Bradshaw et al 2022). Hounding for wolves is allowed under WI Act 169 of 2011. Although statutory legislative changes are beyond WDNR control, they must be considered for future wolf stewardship. I strongly recommend that hounding for wolves be illegal in WI.

The WDNR proposes on page 127 of the Plan to create a designated hound training period on wolves, scheduled to begin after the deer gun season ends, and end in all zones only when the final wolf harvest zone closes. As proposed, if a single wolf harvest zone remains open longer than any other, hound training continues everywhere. I strongly recommend the hound training period must end in all zones at the same time.

As proposed, the hound training period on wolves will be during the wolf breeding season (Mech 2002). This timing will be extremely detrimental, as it will disrupt pair bonding, breeding, and territory boundary defense. The biological impacts of the February 2021 WI wolf hunt, held during the wolves' breeding season, will never be fully understood due to a lack of important biological data collection. Impacts that occurred to the overall WI wolf population from the 2021 hunt, and impacts to specific local packs, cannot be known.

Also as proposed, the hound training period would disrupt wolf winter track count surveys and other collections of population data. I strongly recommend that hounding for wolves be illegal in WI. Until using trailing hounds to pursue wolves is illegal in WI, and if a hound training period is established, I strongly recommend it is not held during the wolf primary reproductive season.

C. The use of recreational hunting as a conflict resolution/depredation control tool is ineffective and inappropriate for science-based wolf stewardship, and WDNR recommendations must be revised. The WDNR briefly explains on page 61 of the draft Plan WI Act 169 of 2011, which mandates a wolf hunting season. Wis. Stats. s. 29.185 directs the WDNR to allow hunting and trapping of wolves if they are not listed on the federal or state endangered and threatened species lists. The statute directs the WDNR to hold a single annual season for both hunting and trapping of wolves, which begins on the first Saturday in November and ends on the last day of the following February. WDNR can set the harvest quota of wolves killed, and the timing and methods to be used. Although there are legislative changes that are beyond the WDNR's control, I strongly recommend WDNR pursue statutory legislative changes for future wolf stewardship and management.

The WDNR states on page 27 of the draft Plan that "...lethal control options may empower local residents and provide a sense of security." This is a false sense of security and may not prevent,

but may exacerbate conflicts (Haber 1996; Treves et al 2016, Santiago-Ávila et al 2018a,b, van Eeden et al 2018b). The WDNR gives the impression to those reading the draft Plan that recreational hunting will decrease wolf depredations. Current scientific evidence supports the ineffective and counterproductive efforts of lethal interventions for conflict mitigation (Miller et al 2016, Treves et al 2016, Eklund et al 2017, Lennox et al 2018, van Eeden et al 2018a,b, Khorozyan and Waltert 2019, Bruns et al 2020). There is strong evidence that non-lethal methods have proven effective in preventing and mitigating wolf predation in the Great Lakes region (Davidson-Nelson & Gehring 2010, Gehring et al. 2010). Much of the scientific evidence and discussion supporting the ineffective nature of lethal control actions is lacking in the WI draft Plan, and must be added to the draft Plan and further discussed.

Lethal management often fails to provide a long-term solution to wolf predation, and has the least effective success rate when compared to non-lethal practices (Treves et al 2016, van Eeden et al 2018, Santiago-Avila et al 2018a, Bruns et al 2020). Published evidence shows that lethal wolf management may be less functionally effective at mitigating subsequent livestock losses than non-lethal deterrents (Treves et al 2016). WI has found this to be true, as WI wolf depredations after the February 2021 hunt were verified at 48 farms, the highest number of individual WI farms to date (WI draft Plan p 74, Figure 22).

A proactive non-lethal approach leads to better conflict mitigation (Eklund et al 2017). WDNR should expand the Integrated Wolf Conflict Management Program recommendations in the draft Plan on p 85 to include recognized effective non-lethal depredation efforts. These have been well funded in MN, and MN Animal and Plant Health Inspection Service (APHIS) reports that "In the two years that MN Wildlife Services' conflict prevention program has existed, there has been no verified wolf damage inside turbo fladry-protected areas or where other non-lethal prevention activities have been deployed." (USDA APHIS Wildlife Services Nonlethal Initiative for Livestock Protection 2022). I strongly suggest WDNR adopt the recommendations of the final MN Wolf Management Plan and conduct research to more effectively address wolf depredation through non-lethal and cost effective means (p 35 Minnesota Wolf Management Plan 2023-2032).

D. Wolf populations are not "remarkably resilient to human-caused mortality" as stated, and proposed WI management actions must be revised. WDNR repeatedly asserts that "Gray wolves have high reproductive potential and populations in general are resilient in the face of severe disruptions or population declines, with the ability to rebound quickly if the disruption is reduced after an event" (pp. 10-13, 20-21 of the draft Plan, citing Hayes and Harestad 2000b, Fuller 2003, USFWS 2020).

I contend wolves exhibit limited reproductive capacity, rather than having a "high reproductive potential" as WDNR states. The reproductive physiology of canids is unique, as the cycle is characterized by extended periods of proestrus and estrus followed by obligatory diestrus and protracted ovarian inactivity (anestrus) (Nagashima and Nucharin 2021). Wolves have one breeding cycle per year, typically with only one litter produced in each pack by the breeding pair (Mech 1970, Mech and Boitani 2003).

WDNR states on page 12 of the draft Plan that "Wolves' ability to disperse long distances allows for populations to readily expand and recolonize vacant habitats as long as human-caused mortality is sustainable" (citing Mech 1995, Boyd and Pletcher 1999, Treves et al 2009, Mech 2017, Hendricks et al 2019). Wolves do not readily expand and recolonize, as dispersal is dangerous (Treves et al 2009). The historic extirpation of wolves in much of North America was due to human-caused mortality (Paquet and Carbyn 2003).

WDNR states on page 123 of the draft Plan "This season will offer the interested public an opportunity to legally harvest wolves, provide the primary mechanism to manage wolf abundance and distribution at the landscape scale and can do so without jeopardizing the long-term sustainability of wolves in the state." There is a "killing for tolerance" hypothesis (Treves 2009) argued by many regulatory agencies. The "facilitated illegal killing" hypothesis, however, is supported by published studies which show that regulatory policies that liberalize legal wolf-killing also increase illegal killing, while regulatory policies that restrict killing and increase protections for wolves mitigate their intentional killing, both legal and illegal (Liberg et al 2012, Santiago et al 2020, Louchouarn et al 2021, Santiago et al 2022).

WDNR cites on p 21 of the draft Plan a study of northern Rocky Mountain wolf populations that were evaluated regarding the effects of public wolf hunts on population recruitment (briefly, the process by which new individuals are added to a population) (Ausband et al 2014). Wolf harvest rates averaged approximately 24%. The study found pup survival decreased from 60% to 38%, with recruitment similarly declining from 3.2 to 1.6 pups per pack, in the years with a public hunt. I contend this is a substantial decline which jeopardizes wolf sustainability.

WDNR states on page 12 of the draft Plan **"**Regardless of mortality cause, wolf pack structure creates resiliency in the event of a pack member's death. Breeding members can be replaced by either an internal pack member or an outside member brought into the pack, and pups can be brought up by remaining pack members (Mech and Boitani 2003)". Current research however, has found that composition within a pack influences pup survival (Ausband et al 2017), and if key individual wolves are killed, this disrupts the breeding pair, reduces the survival of the remaining members, and could cause the pack to dissolve entirely (Creel and Rotella 2010).

WDNR states on page 21 of the draft Plan that "wolf populations are remarkably resilient to human caused mortality, and experience with regulated wolf harvest in WI has largely supported this finding." This statement is inconsistent with published studies. A recently published large scale long-term study determined that human-caused mortality triggers instability in wolf packs in national parks (Cassidy et al 2023). The study evaluated how humans impact individual wolf packs, the biological social unit, as opposed to the larger wolf population.

Cassidy et al (2023) found that humans are clearly altering important aspects of wolf biology in national parks, even if they are not impacting the overall wolf population size. The study evaluated the consequences of human-caused wolf mortalities on two measures of gray wolf biological processes: pack persistence and reproduction. The study contrasted what happened to wolf packs after at least one member was killed by human-causes with packs where no

members died of human-causes. The chance that a pack stayed together to the end of the year decreased by 27% when a pack member died of human causes, and whether or not that pack reproduced the next year decreased by 22%. When a pack leader died, the impact was even greater, with the chance the pack remained intact until the end of the year decreasing by 73%, and pack reproduction decreased by 49%.

The ecological and biological impacts of the February 2021 WI wolf hunt, held during the wolves' breeding season, will never be fully understood due to a lack of important biological data collection. Impacts that occurred to the overall WI wolf population, and impacts to specific local packs, cannot be known. I strongly recommend WDNR must revise their proposed WI wolf hunt management actions, considering the profound impacts that human caused mortality has on wolf pack integrity recently demonstrated by Cassidy et al (2023).

E. Scaled Occupancy Model (SOM): WI wolf population estimate method must be revised, and detailed population monitoring efforts must be reinstated. WDNR historically employed detailed wolf population monitoring which resulted in extensive invaluable population information (pp 47-50, 64 draft Plan). A full description of methods is provided by Wydeven et al (2009). The WDNR began annual overwinter minimum counts of wolves in the winter of 1979-80, and began a wolf monitoring project which effectively ran continuously from 1979 to 2020 (p 48 and 64 draft Plan; Wydeven et al 2009).

As stated on pp 64-65 of the draft Plan, in 2020 a shift to monitor the WI wolf population was used, "A new population abundance estimate approach based on a scaled occupancy model (SOM)" (Stauffer et al 2021). Briefly, the SOM estimates the total area occupied by wolves, combines the average pack territory with zone-specific average pack size, then estimates the entire state wolf population. The SOM assumes wolves are present but undetected. The SOM is based on a probability that a territory/area is occupied by wolves. Uncertainties associated with the SOM include how big are WI wolf packs in various parts of the state? What happens when packs are disrupted, or disappear? What are the consequences for packs after the February 2021 WI hunt? These uncertainties must be included in the model and addressed.

The SOM generated data is used by WDNR to set the quota of wolves to be killed in a legal hunt. Importantly, the SOM has not been tested or validated with hunting mortality factored into it. The SOM uses data from winter track counts, which is good. The SOM uses a "most likely value" rather than a value based on a minimum count, which is not good. There is uncertainty about population estimates generated by the SOM, especially at the zone level. Basing wolf kill quotas on the "most likely value" creates a significant risk of over-harvest from a legal hunt.

A recent critique (Treves and Santiago-Ávila, 2023) of the SOM concluded "… the WI method would systematically overestimate wolf abundance by large (but currently incalculable) margins. Because Wisconsin, similar to other states, not only changed to unverified methods but also implemented widespread wolf killing, shortcomings in their estimates of wolf abundance may have far-reaching consequences for population viability."

I strongly recommend the WDNR SOM population estimate method must be revised, and detailed population monitoring efforts must be reinstated. Specifically:
1. that the SOM must be tested and verified under hunting conditions.
2. that the SOM use WI wolf population estimates at the low point, using the lowest level of credible interval, ensuring a conservative as possible population estimate.
3. that WI wolf kill quotas be determined using the SOM lower 95% credible level.
4. that WI continue to use both the minimum winter count, based on winter track surveys and summer howl surveys, and SOM population estimates simultaneously for 3 years, with hunting conditions.

F. Revise and expand the information under "Ecosystem Services" in the draft Plan, p 13. The ecological benefits wolves provide are associated with their presence and density on the landscape. Two recent studies point to the increased benefits of allowing wolf predators to naturally regulate their prey populations, with beneficial effects resulting for the prey populations. I suggest the WDNR use more recent and pertinent scientific information under the Ecosystem Services portion of the draft Plan on p 13, and include these studies:
1. Tanner et al (2019) found reduced levels of indirect transmission of disease by selective wolf predation in northern Spain. The study found a much lower level of tuberculosis (TB) in wild boars where wolves are present, and less transmission of TB to livestock.
2. Hoy et al. (2022) found selective pressure, through wolf predation, against genes associated with developing severe osteoarthritis in moose prey populations on Isle Royale National Park. Hoy et al (2022) stated "The evidence we present for predation's influence on the health of prey populations is also relevant for policy-related arguments about refraining from intensively hunting wolf populations."

III. Aspects of the draft Wisconsin Wolf Management Plan to Be Added:
A. Include a research item: Wolves and Chronic Wasting Disease: Assess and measure the possible effects of wolves on chronic wasting disease presence and prevalence by establishing temporary Wolf/CWD surveillance zones. WDNR briefly discusses on pages 15-16 of the draft Plan "Selective Predation and Chronic Wasting Disease" (CWD) and states "whether predators can truly reduce CWD prevalence and spread remains unknown and more research is needed." Peter David and Kerry Beheler suggest that a research proposal which specifically addresses this unknown be included in the draft WI wolf Plan.

There is significant overlap between current WI CWD infected deer locations and wolf range (WDNR map 9/2022. https://p.widencdn.net/6ixtwa/cwdAffectedCountiesMap). We suggest WDNR include in the draft Plan that temporary, local, small-scale, harvest/research/surveillance zones around **newly documented CWD outbreaks within wolf range** be established. Within these temporary Wolf/CWD surveillance zones, wolf harvest would be kept to an absolute minimum in order to maximize the opportunity for wolves to potentially control CWD expansion. These temporary Wolf/CWD surveillance zones would be focus areas for intensive data collection, surveillance and research, and paired with minimal wolf harvest to document relationships between wolves, deer, and CWD.

This is an opportunity to document and quantitate the role that wolves have in possibly regulating the spread of CWD in WI. Wolf and deer sample and data collections would be implemented, and collaborative studies with other regions and institutions would be initiated. Establishing temporary Wolf/CWD surveillance zones satisfies objectives of the WI wolf draft Plan, specifically Objective A: Ensure a Healthy and Sustainable Wolf Population to Fulfill its Ecological Role; Objective C: Provide Multiple Benefits Associated with the Wolf Population; Objective D: Increase Public Understanding of Wolves in Wisconsin; and Objective E: Conduct Scientific Research to Inform Wolf Management and Stewardship.

Establishing temporary Wolf/CWD surveillance zones also satisfies the WDNR CWD Response Plan goal to "enhance scientific information about CWD and continue statewide surveillance in areas where the disease is not known to exist, using new approaches to detection and surveillance that balance efficiency and efficacy." The WDNR CWD Response Plan follows an adaptive response strategy as "it is essential because the understanding of both CWD epidemiology and the efficacy of CWD management techniques in free-ranging populations is still developing." (WDNR CWD Response Plan 2010).

Effective measures for controlling CWD remain elusive (Wild et al 2011). Supporting natural control of CWD infected animals by studying WI wolf predation is an area that deserves further study. Predation as a means of natural control has a theoretical basis (Wild et al 2011, Brandell et al 2022), and studies have found predators including mountain lions and coyotes likely select for disease-compromised cervids (Miller et al 2008, Krumm et al 2010, DeVivo et al 2017). Removal of infected animals by predators could complement broader CWD management efforts (Baune et al 2021). Until a full scientific understanding of the ability of wolves to limit CWD is available, a conservative approach towards the stewardship of both deer and wolves would be to assume these benefits exist. The establishment of temporary Wolf/CWD surveillance zones in WI wolf range would begin the research into these benefits.

B. Expand and increase wolf collaborative studies and sample and data collections from all wolves, and train volunteer personnel. Collaboration among tribal nations and natural resource agencies is paramount for wolf stewardship and scientific data collection. The upper Great Lakes wolf population encompasses areas of Canada, Michigan, MN, and WI. I strongly recommend an increased effort to establish and expand collaborative wolf studies to share regional population information, to broaden and increase funding sources for such studies, and to be flexible as research tools are refined.

I strongly recommend an increased effort to live capture and radio-collar WI wolves. There are currently only 12 radio-collared wolves (draft Plan p 21). This sample size must be increased for accuracy and statistical predictions. Extensive and invaluable population, health, and mortality information has been historically gathered from WI radio-collared wolves (draft Plan pp 51-53, Tables 6 and 7). Continuing and increasing radio-collaring efforts, and collaborating with tribal nations and other agencies to facilitate combined analysis, will increase regional wolf stewardship.

I strongly recommend a continued and increased effort to collect basic demographic data and biological samples from all non-hunter killed wolves, including all vehicle killed, depredation control, or other types of wolf mortalities. Historically, WI wolf health monitoring included collection and analysis from live-captured wolves, wolf scats, and necropsies of found dead and depredation killed wolves (draft Plan p 114). Basic information included location, sex and age, and cause of death. Samples collected included reproductive tracts from females, and tissues for genetic, contaminant, parasitic, and other health analyses. Potential new contaminant concerns that have not been fully evaluated in wolves include exposure levels to neonicotinoid pesticides and PFAS. Toxin concerns that have not been fully evaluated include intentional poisonings, and the widespread use of chocolate at bear bait stations and it's effect on wolves. Chocolate is toxic for many species (Gwaltney-Brandt, S.M. 2022).

If a WI wolf hunt occurs in the future, I strongly urge WDNR to collect basic demographic data and biological samples from all hunter killed wolves. In the February 2021 WI hunt, 218 wolves were registered as legally killed, and 188 were killed by hunters using trailing hounds (86%) (WDNR Wolf Report 2021). Carcasses were only briefly visually inspected when registered, and it is not known how many of the adult females were pregnant or breeding. Less than 10%, or 21, of those wolves were voluntarily surrendered by hunters to the Great Lakes Indian Fish and Wildlife Commission (GLIFWC) for examination. GLIFWC biologists and others performed a basic gross necropsy examination of each wolf following standard anatomic pathology guidelines, which included an external evaluation of the animal, and examination of the internal structures including respiratory, cardiovascular, and digestive systems when applicable. Although it was a relatively small sample size, it was important as it represented an indication of the overall health and condition of WI wolves during the winter months. The GLIFWC report has not been released to date.

I recommend WDNR consider contracting with outside scientific and educational institutions for basic post-mortem analysis and sample collection from dead wolves, excepting those needed for law enforcement cases or diagnostic necropsies. Institutions would include universities and colleges, and other agencies. Personnel can be trained to perform a basic gross necropsy examination and biological sample collection following standard anatomic pathology guidelines. Sample collection personnel can be volunteers, or the collection efforts can be used as training exercises by agency personnel.

IV. Additional Specific Comments on the draft Wisconsin Wolf Management Plan, Objectives and Strategies: The WI draft Plan is organized as an adaptive management plan, with a series of objectives, then strategies and products linked to each objective (draft Plan p 98). I agree the draft Plan should be sensitive to changing ecological and social conditions (draft Plan p 11). I suggest the Plan have a ten year time period, with a mid-point review, to assess implementation and progress of management actions (ten year plan 2023-2032, revise after 5 years).

I strongly recommend the WI draft Plan identify and include budget needs to fully implement their outlined management actions, including the opportunity to secure outside funding and explore policy and funding for evolving wolf depredation and compensation. Funding for the wolf

program should come from sources that reflect all values of wolves, as suggested by the 2023 MN Wolf Plan (MN Wolf Plan p 35).

Table 13 of the WI draft Plan (p 102) is described as "the WI wolf management plan objectives and associated metrics by which to evaluate progress towards those objectives. Metrics may be qualitative or quantitative." I strongly recommend WDNR identify **quantitative** metrics for each objective that have identified data points and can be reviewed annually. Metrics can include pack integrity, relative distribution of wolves, pack size, and other factors that can be quantified to define successful wolf stewardship and management. These metrics can be similar to the quantitative performance measure listed in the 2023 MN Wolf Plan (MN Wolf Plan Table 4, pages 36-37).

Objective A: Ensure a Healthy and Sustainable Wolf Population to Fulfill its Ecological Role (pp 111-114): see Beheler detailed comments p 3-9 of this document, **Review and Recommendations for the Wisconsin Department of Natural Resources draft Wolf Management Plan,** for specifics.

Objective B: Address and Reduce Wolf-Related Conflict (pp 117-122):
Strategy B1: see Beheler detailed comments p 2-3 of this document, **Review and Recommendations for the Wisconsin Department of Natural Resources draft Wolf Management Plan,** for specifics.

Strategy B2: Wolf damage compensation. See Beheler detailed comments p 2-3 of this document, **Review and Recommendations for the Wisconsin Department of Natural Resources draft Wolf Management Plan,** for specifics regarding legislative and administrative rule changes.

Additional comments on **Objective B:** Address and Reduce Wolf-Related Conflict: hunting dog and livestock depredations. WI Act 169 of 2011 mandates that depredation payments are funded directly from the sale of wolf hunting or trapping licenses and application fees (draft Plan p 86). This is an inherent problem, as it maintains an unsuitable and unstable funding mechanism. The 2023 MN Wolf Plan recommends that to administer their wolf program, the MN DNR secure funds and investigate revenue sources in addition to wolf license fees. MN maintains that "Funding for the wolf program should come from a combination of sources that reflect the broad values of wolves in MN" (MN Wolf Plan p 35). I strongly suggest the WDNR follow these MN funding recommendations.

WDNR states in **Objective B** that it may be difficult to maintain downward trends with hunting dog conflicts if hound hunting and training grows substantially by in-state or out of state hunters (draft Plan p 117). WDNR shows that "most conflicts involve bear hunting dogs and occur on public hunting lands when humans are not in close proximity to their dogs" (draft Plan p 80, Figures 26 and 27). An independent 2021 report found that "During the February 2021 hunt wolves were removed primarily from core habitats on public lands where conflicts with pets, livestock or human safety are already rare. There was correspondingly little reduction of

wolf populations in areas of marginal habitat where livestock and pet depredations and human-wolf conflicts are most likely to occur. Based on currently available information and our understanding of wolf populations and behavior, there is little evidence that the February 2021 wolf hunt will significantly reduce human-wolf conflicts." (Wisconsin's Green Fire Conservation Bulletin 2021). As most of the bear hunting dog depredations occur in wolf core areas of public land, I recommend WDNR discontinue the $2500 compensation payment, mandated by WI Act 169 of 2011, for bear hunting dogs killed in wolf core areas on public lands.

Regarding livestock depredation, MN livestock owners are currently reimbursed through general funds. The 2023 MN Wolf Plan, however, recommends alternative funding for livestock depredation, with no further reliance on government funded wolf control and livestock compensation payments (MN Wolf Plan p 35). I strongly recommend WI seek alternative funding for livestock compensation.

Objective C: Provide Multiple Benefits Associated with the Wolf Population (pp 123- 127): Strategies C1-CE: I agree with most of these Strategies. Also see Beheler comments p 1-8 of this document, **Review and Recommendations for the Wisconsin Department of Natural Resources draft Wolf Management Plan,** for specifics.

Strategy C2h: designated hound training season (p 127). I do not agree with this Strategy. See Beheler comments p 1-2 of this document, **Review and Recommendations for the Wisconsin Department of Natural Resources draft Wolf Management Plan,** for specifics.

Objective D: Increase Public Understanding of Wolves in Wisconsin (pp 129-130): WDNR should significantly expand this Objective and associated Strategies D1-D3. I specifically recommend collaboration with non-consumptive public education groups and educational institutions.

Objective E: Conduct Scientific Research to Inform Wolf Management and Stewardship (pp 132-136): see Beheler detailed comments p 1-9 of this document, **Review and Recommendations for the Wisconsin Department of Natural Resources draft Wolf Management Plan,** for specifics.

Objective F: Provide leadership in collaborative and science-based wolf management in Wisconsin (pp 136-139): see Beheler detailed comments p 1-9 of this document, **Review and Recommendations for the Wisconsin Department of Natural Resources draft Wolf Management Plan,** for specifics.

2/20/2023

We are writing to express our concerns about a proposed wolf hunting and trapping season. We are absolutely opposed to any potential wolf hunting season. It appears to us that this season is being created to appease a small but vocal minority who it seems want to kill wolves for no good reason other than that they exist.

Hunting wolves with packs of dogs is beyond cruel and inhumane, the mere consideration of this practice is apalling. Trapping is a cruel, sadistic activity, what is the justification supporting this horrific method. As we all are aware, Wisconsin has a sizable 7 billion dollar surplus. How difficult would it be to set aside an account to reimburse those farmers and livestock managers who are experiencing occasional wolf-livestock conflict. In those instances where wolves have become accustomed to preying on stock they of course would have to be removed. A specialized gun hunt to remove offending animals would suffice. If there is a demonstrated proven need to reduce the wolf population, gun hunting is the only humane, reasonable method. No traps, no dogs, period.

We are by no means anti-hunting and are sport shooting enthusiasts, but this sort of gratuitous killing for the sake of killing destroys the image of legitimate hunters. A hunt such as this would be an indelible stain on Wisconsin's national image of a humane, well managed sportsmans paradise.

We believe there is overwhelming opposition generally across the state to a wolf hunt.

Thank you for considering our input.

George W. Berdine

Mr. Johnson,

I appreciate the opportunity for public comment on Wisconsin's Wolf Management Draft Plan. I know there were many people who spent a lot of time coming up with this draft. I and many others appreciate all of the cooperation between individuals and organizations to come together on this issue and develop a draft.

With all of that being said, it is my opinion that this draft needs to be thrown out and reworked from scratch. While the draft is ornately written, it fails to conceal the underlying theme: there is no plan. What plan there is certainly cannot be referred to as a "management" plan.

The proposed draft is a shell of arbitrary objectives and shifting goals. With the absence of numeric population goals, the plan is seemingly a population growth plan with provisions for conflict management. Conflicts which will continue to increase as the population grows and expands into areas once designated as inappropriate habitat for wolves; areas of higher human and livestock population density.

The draft rationalizes the lack of a numeric population goal by comparing wolf management to the management of deer, grouse, turkey and other species, excluding elk. It goes on to state that " elk in the state continue to be managed in a recovery status, as were wolves in the past, and numeric goals may not be appropriate for Wisconsin elk in the future." This is a relatively dishonest comparison when you consider that the original management goal of 350 wolves set in 1999 was never actually adhered to. The first wolf hunt came in 2012 when there were 815 wolves in the state and the state harvest quota was 116. Even if the harvest quota had been met, the population would have still been at 200% of the original management goal. Another example of arbitrary management goals can be seen in the comparison of the 2014 and 2021 wolf hunts. In 2014 there were an estimated 660 wolves in the state of Wisconsin and the state harvest quota was 150. In 2021 (the next year that a wolf hunt was allowed), there were 1,126 wolves in the state of Wisconsin and the state harvest quota was 119. While the population was 70% higher, the harvest quota was 20% lower. Yet another illustration of not truly following a numeric management system is the exclusion of "reservation wolves" from the population estimates when developing quotas. Being that there are no barriers preventing wildlife from traversing in and out of designated Reservation areas, this unnecessarily skews the population estimates. The lack of science based management is apparent even during the time period when wolves were being numerically managed in a recovery status. Loosening the management objectives and removing numeric population goals is moving in the opposite direction of where we should be going.

Altering wolf management zones and expanding their boundaries into Marathon County and central parts of the state is an unreasonable component of the draft as well. Reclassifying these areas to Secondary Range from inappropriate habitat shows a continued lack of science based reasoning and goes against conflict management goals.

While there is a wealth of scientific data provided within the report and the draft itself, it is obvious the “social” factors repeatedly referenced are the larger driving factor in this draft. If this draft were to be accepted as it is currently proposed, Wisconsin wildlife and wolf management will be derailed and will fall even further from science based management to emotion based preservation.

I believe that this draft is unacceptable in its current form and must be thrown out and reworked. I believe it needs to better represent the farmers, outdoorsmen, and rural residents of Wisconsin who not only live in wolf country, but who are affected by wolf populations and management practices. It should be based in science and contain numeric population goals.

Again, I appreciate the opportunity to give my input on this wolf management plan draft.

Thank you

Dan Berg
President, Price County Farm Bureau

Comments on the Wisconsin (11/10/2022 Draft) Wolf Management Plan

As of 1/3/2023

1. ITEM: (page #107 end of 2nd Paragraph): *"It is recommended that only wolves legally harvested by licensed hunters or trappers during the wolf season (i.e., not those removed for depredation controls, vehicle kills, etc.) count towards the subzone limit."*

   Comment: Why not count all dead wolves toward this limit? Every death affects the overall population number.

2. ITEM: (Zones 3 and 4, page #105):
   "The plan recommends that the leading objectives within these zones be twofold: addressing and reducing wolf-related conflicts (Objective B) and providing multiple benefits associated with the wolf population (Objective C). Ensuring a healthy and sustainable wolf population to fulfill its ecological role (Objective A) is also recommended to be considered in these zones, *but decision-making primarily be guided by the leading objectives (B and C). Accordingly, wolf harvest rates in these zones are recommended to be generally higher than prescribed in zones 1, 2 and 5 to provide ample harvest opportunity and potentially reduce wolf densities*, while simultaneously not jeopardizing the long-term persistence of some wolf packs within these zones."

   Comment: The emphasis here seems to be way too strong on "hunting" and "reduction of numbers" rather than focusing on just "reducing wolf-related conflicts". The goal of ensuring healthy wolf population should be equal to the other priorities.

3. ITEM: (Zone #6, page 105): "Because wolf packs will generally be limited in this zone due to reduced habitat quality, ensuring a healthy and sustainable wolf population to fulfill its ecological role (Objective A) is recommended to be given a reduced role in decision-making for this zone. *Accordingly, the plan recommends that wolf harvesting licenses be readily available in this zone to allow local control over wolf occupancy and density in this zone."*

   Comment: Why is "local" control given as preferred to State DNR control? Who would be allowed to administer this "local control"? What if this "local control" person or committee is vehemently "anti-wolf"?

4. ITEM: (Page #111: Product A1b): "Ensure the late-winter wolf population abundance is responsibly maintained above federal and state listing thresholds: … *Similarly, the current state threatened species level set by the 1999/2007 state wolf management plan is a late winter count of 250 wolves in the state outside of tribal reservations."*

   Comment: People want to be sure wolves are protected and maintained at the levels they now exist (approximately 850 to 1200 animals). Any mention of a downside limit as low as 250 (or lower) is totally destructive to this whole effort and should be removed. You have (rightly) stayed away from mentioning any limits elsewhere in this report, why mention it now? **If a downside limit number is absolutely required to be listed, then I would suggest something in the 950 range. Anything lower and you will not have solved this wolf numbers conflict at all,** (while actually doing an excellent job on everything else in this report !!!!

Thank you all so much for doing the work on this report!!
A wonderful effort !!

P.S. I am not a hunter, but I enjoy travelling the state, hiking, and taking wildlife photos.

DNR Wolf Plan Comments: Feb. 16, 2023

This is to let the DNR Know that they should have a Wolf hunting and Trapping Season to save the deer and ELK herd in Northern Wi. or what's left.

It's hard to believe that thousands of dollars were spent on the ELK just to be food for the wolves.

The wolf population should be Kept to 350 wolves in the state of Wisconsin.

Our hunting camp is in northern Wi. and there are 12 of us in the camp. If you want us to Keep hunting you better do Something about the Wolves.

Kenneth Brunner
Geneva Brunner
and the
12 members of the Hunting Camp.

January 24, 2023

Wis DNR Wolf Management

Public Input

As a lifelong Wisconsin resident, I have always treasured my "walks in the woods" with my canine friends. Due to the large numbers of wolves in northwestern Wisconsin, I no longer feel relaxed and enjoy the outdoors, but instead am constantly alert to any danger to my dog. I served in the army and woodland walks are beginning to feel like a military patrol – constantly on the alert.

Much of the support for the ever increasing size of the wolf population live in urban areas. I say to them, come on up and live with them. The wolf is becoming increasingly bold and show no fear of humans. Some of the "co-existence" recommendations are absurd. For instance don't let your dog out after dark. In northern Wisconsin that's 16-17 hours for most of the winter. Ridiculous.

When the original wolf management plan was released in the 80's I told Adrian Wydeven that the plan's prediction that suitable wolf habitat could be found only in some portions of the Nicolet and Chequamegon National forests was incorrect. Sadly I was correct. The wolf would prove to be (and has) just as adaptable as the coyote. Trail cams on my southern Marquette County farm now frequently have images of wolves. Perhaps when a pack takes up residence in the Arboretum, some of our concerns will be appreciated.

I also told him that the target population of 350 would be rapidly surpassed and the wolf supporters would say that is good and fight any efforts at control. Sadly that is true.

Give the woods back to the people for relaxing recreation and manage the population to reasonable levels where seeing a wolf is a rarity, not a common occurrence.

Jim Bryan

Dept. of Natural Resources
Wolf Management Plan
101 S Webster St.
Madison, WI 53707

February 13, 2023

Dear DNR:

My wife and I have looked at the proposed Wolf Management Plan and would like our voices heard. The plan appears very comprehensive. As a lifeline resident of Wisconsin, my most sincere hope is that we honor and support Wolves miraculous recovery. The Packs are a blessing, a gift, and a second chance.

My concern is how will this lengthy report protect Wolves from another slaughter at the hands of wolf haters from around the Country? Scientific knowledge didn't protect pregnant females from being hounded to exhaustion, day and night, by dogs. And awareness of Wolves as a keystone species essential to our ecosystem didn't keep them from being decimated. Did the DNR take any action whatsoever during this time? The Wolves never had a chance.

As part of the plan, we should add an apology to members of Wisconsin Tribes for allowing destruction of creatures they consider respected relatives. Also, every guy who has a relatively new stuffed wolf head on his wall should pay reparations to the rest of us, whose resources they plundered with no accountability. Having faith that the State of Wisconsin does the right thing regarding protection of wildlife will be difficult to get back.

Respectfully Yours

Rodney S Campbell

Attention Deputy Secretary Barry and Randy Johnson:

I have voiced my concern in the past, and I would like to add my name to the growing number of Wisconsin landowners/hunters to petition your 167 page Draft Wolf Management Plan!!

I am a former graduate of the University of Wisconsin Stevens Point(1989). I graduated with a BS Degree in Wildlife Management and Natural Resource Management. Some of my instructors were Christine Thomas, Dean Trainor, and Neal Payne. They along with many other educators at the College of Natural Resources taught me the principles of wildlife management, population dynamics,wildlife survey methods, integrated resource management, etc.

The DNR is not applying sound scientific management principles/data to manage the growing wolf population in Wisconsin!

As Laurie Groskoft states in the latest issue of On Wisconsin Outdoors, Ms. Groskoft and thousands upon thousands of Wisconsin Sportsmen/Hunters are dumbfounded with disbelief regarding the DNR's Wolf Plan, and their total lack of urgency/panic towards the growing population of wolves in Wisconsin.

I agree with every word Dick Ellis and John Ellis put to paper in the January/February edition of On Wisconsin Outdoors. I also petition with Laurie Groskoft and the rest of Wisconsin Wildlife Federation to revise your Wolf Draft to address all the points made by the WWF to challenge your draft.

Wolves are wiping out the deer herds in Wisconsin, Michigan and Minnesota. Wolves are encroaching human occupancy more each year, and putting human safety at risk. Wolf depredation on domestic dogs, and farm animals has escalated to out of control incidents/reports.
Wolf depredation is directly linked to the decline of deer hunters in the woods. As a result of wolf depredation: no deer, loss of hunter numbers and interest to participate in the sport, and a substantial loss of revenue.

The DNR needs to wake up, do the job our taxes/funding pay you to do, and adopt/address a plan to control(manage) our wolf population!!
The only way to do that is with an annual harvest of at least 350 wolves(that number should be 500-600 in my opinion!!).

DICK ELLIS

Wisconsin Wildlife Federation challenges DNR Draft Wolf Management Plan

Wisconsin DNR posted a 167-page Draft Wolf Management Plan on November 11, 2022 that eliminates "a single numeric population goal". DNR requested that respondents "invest time in reading the draft before submitting feedback". Feedback, for reasons unknown, is accepted from Wisconsin residents and non-residents.

On Wisconsin Outdoors (OWO) received the letter to follow from the Wisconsin Wildlife Federation (WWF) responding to the plan. The WWF represents 211 affiliated grassroots hunting, angling and sporting conservation clubs throughout Wisconsin. *OWO* strongly recommends that your investment of time goes to reading the 1-1/2 pages below prior to connecting with DNR Draft Plan though the DNR website.

OWO sought input on the DNR plan from Laurie Groskopf, who we have learned to trust as a wolf management source of expertise. Groskopf is on the Board of Directors for the WWF, and a delegate to the Wisconsin Conservation Congress but stressed that she is commenting as an individual and not as a representative of any organization.

"My main reaction is disbelief that the spread of wolves and conflicts has not been recognized as the threat to rural life it is," she said. "L. David Mech, the world's longest and most experienced wolf researcher, said 'Some zones for some periods can support total protection (of wolves), whereas in others, wolf numbers will have to be reduced to various degrees or removed. They are prolific, disperse long distances, readily recolonize new areas where humans allow them, and are difficult to control when populations become established."

"All of this is lost on the WDNR. DNR uses no science but makes the decision to extensively enlarge what they define as suitable wolf habitat. They use only the fact that wolves live there, so in their mind, it must be suitable habitat."

In the Wisconsin Wolf Management Plan approved in 1999 and 2007, the population goal was 350 wolves. DNR is currently mandated by law to manage state wolf numbers to 350. Thirty-six Wisconsin County Boards have passed resolutions supporting a wolf goal of 350 or less. These 36 county boards are the elected representatives of 1,266,000 Wisconsin citizens.

DNR is using a 2022 "Social Science" Survey to claim majority public support for a wolf population clearly growing and expanding in Wisconsin. Groskopf pointed to the 2022 Spring Hearings, where Wisconsin residents approved a wolf goal of 350 or less (in favor: 12,978. Against: 6,410), a resolution supported in 69 of the state's 72 counties.

"For reasons I don't comprehend, the DNR is deaf to these and other opinions that the wolf population needs to be limited and controlled," Groskopf said. "As every wolf expert said at an International Wolf Conference in October, 2022, wolves are fine in areas with minimal human presence and enough game to eat. However, Wisconsin has by far the highest human density of any wolf-recovered state. Unfortunately, the DNR is promoting wolf persecution by insisting wolves be allowed to occupy all or portions of 37 counties in Wisconsin, with the great possibility they will expand into adjacent counties and states. There are no controls on their numbers. Very sad for the wolves. Very sad for people in wolf-occupied areas."

As the WWF states: The draft plan allows for a subjective process for managing wolves. The population goal was established in the 1999 plan due to lack of confidence in a subjective wolf management strategy. There is no accountability without a numeric population goal. The only scientific analysis of wolf habitat done to-date of Wisconsin landscape quantified the social carrying capacity as 350 wolves. The Wisconsin Wildlife Federation strongly requests maintaining the numeric population goal of 350 wolves in the final plan.

JOHN ELLIS

DNR Mismanagement goes far beyond Wolves

In the Winter 2022 edition of *Wisconsin Natural Resources Magazine*, Dana Fulton Porter writes "Due to climate change, the ice fishing season in Wisconsin is about 24 days shorter than it was in the 1970's." Let that sink in for a moment, and use your judgment. You don't have to be a scientist to know that Dana's statement is ridiculous. But it's a great illustration of how Wisconsin DNR mismanagement, and misinformation, goes far beyond wolves. It's everywhere.

December 10, 2022

Sarah Barry
Deputy Secretary
Wisconsin Dept. of Natural Resources
101 S. Webster St.
Madison, WI 53707-7921

Dear Deputy Secretary Barry,

At our Board meeting today, the Wisconsin Wildlife Federation, with more than 211 affiliated grassroots hunting, angling, and sporting conservation clubs and alliances throughout the state, approved the following response to the WDNR 2022 Draft Wolf Management Plan and requests the Wisconsin Department of Natural Resources take the necessary actions to address the following points in a revised draft or final plan:

Public Comment:

1. The current 60-day public comment period in not an adequate amount of time to gather input considering the timing of the release overlaps with hunting seasons and multiple holidays. We request the timeline be extended to 90-days.
2. Not all residents have email or computer access in their homes. For this reason, we request the WI DNR provide multiple and widely distributed announcements of opportunities and methods for public input along with comment period deadlines.
3. There is no means for submitting additional supporting information to the WI DNR for consideration in the draft plan. The Wisconsin Wildlife Federation requests the WI DNR provide the public with an email and mailing address to submit comments and additional supporting information.
4. The Wisconsin Wildlife Federation strongly requests the WI DNR hold public hearings across the state and hold more in wolf affected zones for input on the draft plan.

Inclusion/Exclusion:

5. There is no provision for the inclusion of comments from county and local governments into the draft plan. Many county and local governments have taken positions on wolf population goals and must be included in the process.
6. A functional advisory committee with a balanced mix of impacted stakeholders would vastly improve this ongoing process.

Public Survey Methodology:

7. The public survey does not adequately represent those actively impacted by wolves. Use of county and zip codes to select samples does not accurately reflect those exposed to wolves and impacted by wolves. We request the WI DNR actively seek out those impacted by wolves and place greater emphasis on their perspective.
8. Survey design is flawed. Survey length discourages responses from some individuals. Terminology is undefined and could be seen as biased. Some questions lack balance in positive and negative responses, causing an imbalance in responses. All these features of the survey alienate some individuals causing them to not respond.

Population Estimates:

9. Approximately 40% of the wolf tracking units are not tracked to the required three-time standard and not all units are

CONTINUED ON PAGE 19

WWF, *FROM PAGE 18*

tracked. This lends itself to under-counting and under-reporting wolf population in those wolf tracking units.

10. Lone and dispersing wolves are not counted in the current population model as is done in western states. Some states add 12% or 15% to their estimates to account for lone and dispersing wolves. We urge lone wolves be included in Wisconsin's population estimate.
11. The WI DNR is not taking full advantage of public reporting of wolf sightings. The online tool for reporting should be better advertised and the WI DNR should clarify that personal information is protected and not available as public record.
12. GPS collar tracking provides the WI DNR with useful information on travel patterns and pack locations for counting. Increased use of GPS collars should be considered.

Conflict Management:

13. The draft management plan is passive and lacks active conflict management for depredations of non-agricultural domestic animals such as dogs and other pets. Increased harvest is not a method identified in the draft plan to reduce such depredations. Include targeted population reduction in areas of heavy depredation of dogs and other non-agricultural domestic animals. This should include all legal methods of harvest for targeted population reductions.
14. The draft plan does not address a numeric conflict reduction goal. We request a goal be set and included in the plan so effectiveness of methods can be measured.
15. The draft plan appears to have biases against hunting with dogs. Hunting with hounds has the same statutory and state constitutional protections as agriculture and should have equal active measures preventing depredations.
16. We oppose the plan wording encouraging low road densities in large tracts of public lands, which is another means to prevent hunting, fishing, trapping, and other public land use opportunities.
17. We oppose the plan wording that implies hunting conflicts are the fault of the hunter. The draft plan needs to address using population management of wolves as a method to reduce hunting conflicts. Hunters have Constitutional rights to hunt lands open to them despite the presence of wolves.
18. Currently there are multiple systems for sending alerts for livestock, hunting dogs, and non-agricultural animals, but the plan is missing human health and safety alerts. Receiving the same notification with a 4-mile radius map is necessary to help prevent potential conflicts for land users, pet owners, and dog hunters around those areas. We request the WI DNR provide equal notifications for equal protections for all land users.
19. Those who have personally experienced conflicts with wolves may have traumatic experiences and stresses. The psychological impacts on humans caused by livestock and domestic depredations by wolves is real and needs to be considered. The draft plan ignores the psychological impacts wolf conflicts have on humans and this needs to be addressed in the plan.

Zone Changes:

20. The plan includes the creation of buffer zones surrounding reservations, effectively giving the management of the wolf population on both public and private lands to the tribes. We oppose the creation of buffer zones surrounding reservations that would take away the rights of private landowners and public land stakeholders. We also oppose giving away wildlife management authority.
21. The agricultural areas in these newly created buffer zones in the draft plan will go largely unprotected and have inadequate protections for pets and livestock. Private landowners will have unequal treatment under the law for which they are protected under the Constitution.
22. The zone restructure is now based on wolf occupancy and not based on suitable habitat. The unmanaged wolf population has forced wolves out of prime suitable habitat into inappropriate areas, creating conflicts. Not all areas are appropriate to have wolves. We request the zone structure return to the original science-based, habitat-based zones.

Goal Statement/Objectives:

23. The Goal Statement in the draft plan does not address where wolves are appropriate. The draft plan needs to take a hard look into what is good for wolves and what is good for humans. Low interactions between the two are best. Wolves should only reside in high-quality wolf habitat and not be managed to the maximum biological carrying capacity. No other species in Wisconsin is managed to its maximum biological carrying capacity.
24. The draft plan implies the elimination of hunting with dogs which is Constitutionally protected. It also implies wolves have more rights to the land than hunters. This narrative is not science-based and all such implications should be removed.
25. Objective B is missing long-term controls for agricultural conflicts. Wolves are known to move down the road and create conflicts with just short-term controls.
26. The goal statement or objectives do not address any form of population control. The official position of the Wisconsin Wildlife Federation is a population goal of 350 wolves in the State of Wisconsin. We strongly request the numeric population goal of 350 wolves be maintained in the final plan.

Numerical Population Goal:

27. The draft plan allows for a subjective process for managing wolves. The population goal was established in the 1999 plan due to lack of confidence in a subjective wolf management strategy. There is no accountability without a numeric population goal. The only scientific analysis of wolf habitat done to-date of Wisconsin landscape quantified the social carrying capacity as 350 wolves. The Wisconsin Wildlife Federation strongly requests maintaining the numeric population goal of 350 wolves in the final plan.
28. For increased accountability the population goal needs to have a timeline for completion. The goal timeline allows measuring of progress towards meeting the set population goal with milestones along the way. We request a population goal timeline be added to the plan.

Quotas/Permits:

29. The western states have 13 years of harvest data in establishing quotas to reach their wolf population goals. We recommend including this data in the draft plan to aid in establishing quotas.
30. Permit issuing methodology should be based on the likely harvest methods used in the season they will be issued.
31. Western states have been unable to reduce their wolf numbers consistently despite high levels of human take. As wolf expert David Mech said, "Wolves are prolific, disperse long distances, readily recolonize new areas where humans will allow them, and are difficult to control when populations become established."

Delisting:

32. For lethal wolf conflict control and population management to take place federal delisting is required. To-date the Wisconsin Department of Natural Resources has had no visible involvement in planning, researching, and federal delisting efforts with the USFWS or with legal representation in delisting efforts. The Wisconsin Wildlife Federation strongly requests the WI DNR have a strong and visible presence, and active involvement in all federal delisting efforts that impact Wisconsin and in support of all other states actively working towards delisting wolves in their states.

The Wisconsin Wildlife Federation requests the Wisconsin Department of Natural Resources incorporate the above actions and requests for updates into the 2022 Final Wolf Management Plan.

Sincerely yours,

TO WHOM IT MAY CONCERN...

THE CURRENT PLAN ALLOWS SOVEREIGN NATIONS CONTROL OVER PRIVATE PROPERTY WOLF MANAGEMENT. PRIVATE PROPERTY MANAGERS SHOULD BE ABLE TO HAVE A SAY IN WOLF MANAGEMENT IN THEIR AREA.

ALSO, THE CURRENT PLAN HAS NO POPULATION CONTROL GOAL OR TRIGGER FOR POPULATION REDUCTION IF NEED BE. HUMANS HAVE TAKEN OVER A PORTION OF THE PREDATORY RESPONSIBILITY IN CONTROLLING DEER NUMBERS THROUGH ESTABLISHED HUNTING SEASONS. AN UNREGULATED POPULATION IS PRONE TO INCREASE IN SIZE & RANGE, AFFECTING NUMEROUS WISCONSINITES IF NOT MAINTAINED AT A SUITABLE LEVEL.

CURRENT ESTIMATES HAVE SAID THE STATE POPULATION IS APPROXIMATELY 1000 ANIMALS. THOSE ALREADY LIVING IN THE WOLF RANGE ALREADY FEEL THE NEGATIVE EFFECTS. THEY NEED TO BE HEARD.

I ASK THAT THESE ISSUES BE ADDRESSED, AND THAT THE CURRENT WOLF MANAGEMENT PLAN NOT BE PASSED.

THANK YOU FOR YOUR TIME.

Logan Christel

Re: Review of the "Draft Wolf Management Plan 2022"

I want to start by commending you and your Wisconsin Department of Natural Resources (WDNR) team on undertaking the difficult assignment of drafting a Wolf Management Plan for Wisconsin. As an interested citizen of Wisconsin, and a former Professor of Wildlife Ecology, I feel I am in a somewhat unique position to provide input and helpful evaluation of that effort. My objective was to use my professional knowledge and experience to aid WDNR in producing the most defendable management plan possible. As you are aware I have also provided this input to the Wildlife Working Group of Wisconsin Green Fire (WGF) and some of my comments have been incorporated into their review. But what follows is my personal technical review, along with general thoughts and impressions. To be clear, I did not do an exhaustive literature search to support each point. In most cases I noted the pages or sections where I first reacted to a point or found issues. Feel free to incorporate verbatim any thoughts that you find useful.

Overall, the WDNR team produced a Draft Plan that is comprehensive, objective, and meets high professional standards. Deciding on the "right" course of action for conservation and management of wolves in Wisconsin, not to mention "who gets to decide" is a daunting task. Various views are expressed by the range of stakeholders, often resulting in diametrically opposed preferred management and outcomes. The WDNR has the responsibility to consider alternatives but eventually "the public," through the Natural Resources Board and political process "decides" the course of action. The Draft Plan largely follows the "North American model" (NAM) of wildlife management, i.e. scientific management-based on observation and data, accompanied by analytical evaluation and modeling. Traditionally the NAM approach is goal oriented. But the plan addresses the need to understand and attempts to compromise constituent viewpoints, especially those based on traditional ecological knowledge (TEK) of indigenous cultures. TEK is founded in long-term observation that is personal and cultural emerging from living as part of ecosystem. In contrast to NAM, it is less goal oriented. I made some specific comments about this at the end of this review.

After reading my notes I decided it would be useful to group my comments into themes.

Theme 1: Population ecology

Pages 13-15: this section focuses on the importance of and evidence for trophic cascades. The authors have provided appropriate caveats, especially with respect to human impacted landscapes. The concept has been around since classic literature (Paine 1966). The idea has had an important influence on community ecology, especially with respect to the role of predation. For example, it underlies the meso-predator release ideas (Crooks and Soule 1999) applied to carnivore communities. But the latter literature is often based on circumstantial evidence rather than experimental evidence (or at least with some controlled comparison). The Draft Plan not surprisingly relies heavily on the literature on the effects of wolves on carnivore communities and trophic cascades in Yellowstone, a literature which has been both enlightening and which also has generated lots of scientific controversy. I often cite the Kluane boreal forest studies (Sinclair and Krebs 2001) which explore the complexities of the trophic relationships and indicate the non-linear nature of the effects—sometime top down, sometimes bottom up, almost always a mixture of both. There is also a large literature from European studies.

Page 17: I'd mention the importance of life history, with respect to compensatory and additive mortality, though it might not be relevant to this paragraph. An additional source of mortality (e.g. natural predation, harvest) can be compensatory if the species has a "fast life history" (i.e. there is lots of "room" for compensation if there is high turnover, high mortality). But for "slow life history" species (long-lived, we used to say K-selected), additional mortality sources are almost always additive. Although large carnivores can be somewhat resilient to harvest, it is easy to exceed the additive threshold.

Page 19: I haven't kept up with the wolf literature as much as I have for smaller carnivores so I was a little surprised at the rates of increase quoted (as much as 29%, λ=1.29). It's probably worth mentioning that such rates can be highly variable, and that the distribution on estimated lambda is skewed (not normal). Some populations may have median λ<1, but periodically be "demographically rescued" by an occasional good year or years. At λ=1.29, a "back-of-the-envelope" calculation would suggest sustainable wolf harvest would be ~23%, considerably greater than my experience with bobcats with sustainable long-term harvest rates of <10%.

Page 21: I recalled reading the Stenglein et al (2015) analyses and note here that the conclusions prompted my thinking about accounting for the various growth phases of a population, particularly as growth slows when habitat becomes saturated. I made further comments about integrated population models (IPM) below, regarding the Draft Plan objectives.

Pages 29-37: it is commendable that WDNR has conducted two recent surveys of the public attitudes toward wolves and wolf management. Figs. 10 and 11 reveal that public attitudes are not as polarized as I might have expected. In general I see support for lethal control, though the public seems split on who should execute that control. There does seem to be public trust of the WDNR responsibility for management.

Page 50: Figure 16 could be improved slightly. The legend for the red line should probably be "estimated number of wolves". You mention that beginning in 2020 the estimates were calculated by occupancy

models, about which the public and even some professionals are skeptical or ignorant. I added some comments about OM below.

Page 54: This point is the first mention of a specific population target that were developed during previous planning. The often-quoted target of 350 wolves remains "fixed" in the minds of many constituents. It might be valuable to point out that some of the "target- number thinking" was inherited from the federal designations for the Great Lakes DPS (which is discussed in detail on pages 54-59). Unfortunately, targets and quotas have been a part of the population harvest management literature since the beginning of the wildlife and fishery science and management. It is significant that the Draft Plan avoids stating a fixed population goal. But I think you need to strengthen the narrative for linking to ecological integrity rather than a population number. You should provide specific thinking (metrics) about how you will assess rate of increase (or decrease), dispersal rate, changes in distribution, pack integrity (persistence), and genetic linkages (more below).

Page 65: From what I have seen online and heard in discussions there is a lot of misunderstanding and criticism of Occupancy Modeling (OM). Even among professionals there remains some skepticism regarding statistical estimation approaches rather than "traditional direct counts." I think the Draft Plan should respond to such criticisms by explaining OM more fully. I provide some points below that come to my mind. Often when trying to explain quantitative methods to the naïve, part of the hangup is the word "modeling." The unsophisticated assume that the model is comprised of a series of untested assumptions (viewed by some as fudge factors) to produce estimates. They do not understand that it is more correct to refer to occupancy as a data driven, statistical estimation procedure.
To help clarify we should encourage the Draft Plan to include these points:

- I understood the motivation for the switch to OM, but the lead-in sounds a little too much like it was adopted to save money; I think you could strengthen the opening by emphasizing the rigor and repeatability
- OM was developed by some of the best biostatical minds in wildlife ecology; they have been widely applied and rigorously tested on everything from "beetles to bears"; they are now used not only to estimate population distribution but also vital rates of populations (a good review like Bailey et al. 2014 or some other part of the huge literature should be cited)
- just as the Wisconsin "minimum counts" method applied previously to the problem, OM estimates the number of wolves on the landscape at a fixed point in time, i.e. roughly mid-winter (between Dec-Mar when data is collected)
- both methods can be used to estimate the change from year to year, i.e. between one winter and the next; in its simplest form OM estimates detection probability and probability of occupancy of the sample units; it is not a correct criticism that OM includes hidden assumptions about mortality, illegal kills, reproduction; however in more sophisticated applications such elements can be included though such applications should properly be called Integrated Population Models (IPM, Zipkin and Saunders 2018, more below); when such elements are included the assumptions are on full display, rather than "hidden"
- OM has the distinct advantage of explicitly accounting for differences in detection probability, which minimum counts do not explicitly include
- furthermore, in answer to an often-asked question, the OM methodology explicitly allows using covariates like weather conditions, habitat, presence of disturbance, etc. to model detection,

each year and place, and thus accounts for variation that would influence the estimated occupancy; minimum counts do not explicitly account for these sources of variation.

- and deer prey abundance from the deer zones and counties can be directly incorporated as a covariate on occupancy.
- the result of the OM statistical procedure is estimates with confidence intervals, also not possible with minimum counts; and the Draft Plan should explain how to interpret the "wide" confidence intervals (CI), which some perceive as a weakness rather than a strength.
- the above point is a very important advantage, especially because of the potential value in setting harvest limits; in previous application to bobcats in Iowa I advocated for harvest quotas based on lower CI which is based on the data, and obviously conservative

Page 67-68: beginning of the quota setting explanation. Regarding Table 11, I didn't find the explanation in text that Population Growth is calculated by comparison of Winter Counts from one year to the next. I'd label the column Population Rate of Change (most folks think of growth as +). Although I would prefer "λ" (i.e. 809/815) the public probably would not recognize that this represents a 1% loss from one year to the next. But I think you should be sure they understand that the rate represents the net change from one year to the next year (i.e. the estimates are "observed finite rate of change"). As such they do not incorporate all the little changes (birth and death of individuals) on which the public focuses. But the estimated rates can be defended as encompassing overall population dynamics. Be sure Table 11 is consistent with Fig. 19. Finally, I note that the entries in the last column of Table 11 are proportions, not percentages as labeled.

Page 97: skipping ahead to more points about population principles and harvest, it is at this point that the argument to shift from a "target population goal" to a "response to ecological conditions" goal is presented. This section reads a bit like a "defense of" past numerical goals (easily defined, etc.) though it does try to convince the reader of the difficulties, cost etc. With appropriate introductory sentences, it might be possible to "flip" the first and second paragraphs, making the species conservation, ecological integrity, and conflicts and cultural considerations opportunities the lead points of the paragraph. The section refers to other species managed by adaptive management in Wisconsin but adding citations of other notable examples (the obvious one is waterfowl) would strengthen the argument.

How does (or should?) the plan acknowledge that the Wisconsin legislative requirement for a harvest season is inconsistent with the other states (jurisdictions) that encompass the Great Lakes population?

Page 102: The table of the Objectives is a great summary.

Pages 103-108: The map of zones is very helpful. The description of each zone is well-connected to the previous sections that cover wolf dynamics and constituent concerns

Objective A: As a relative new resident of Wisconsin, I have relatively little specific knowledge of the historical management of wolf harvest. So, most of my comments above are based on my general knowledge of population ecology and management, including other carnivores. But since reading and listening to much of the online objections, I understand that the specifics of the zones and their management produce the most controversy. Perhaps my comments that focus on the goal of sustaining

the wolf population while allowing some harvest and preventing conflicts is not what you will find most useful.

Objective B: Here also I lacked much local knowledge so I had no specific comments. However, I positively note that the subzones enable focusing harvest around some of the problem areas.

Pages 132-135: Especially with respect to Strategies E1 and E4
The strategies advocate for continued comparison of occupancy modeling with other approaches to population abundance monitoring, which is obviously essential. But I didn't see that the section explicitly addressed integrating OM with more "mechanistic" modeling approaches like IPM (e.g. modeling like Stenglein et al, see review in Zipkin and Saunders 2018). As an aside, IPM is often confused with Individual Based Modeling (IBM, DeAngelis and Grimm 2014) which could also be very usefully applied to the wolf system. IPM could incorporate hypothesized estimates of poaching, the effects of pack disruption, dispersal from source zones into marginal zones, etc. Obviously, there may only be bits of data on some of these factors, but of course the advantage of such modeling is the ability to test a range of possibilities (i.e. what if poaching is infrequent versus larger and underestimated). Bottom line, the Draft Plan should specifically encourage research collaborations on OM, IPM, IBM within the WDNR and with college/university partners.

<u>Theme 2: Landscape ecology</u>

Page 12: I recognize that the goal of the Draft Plan is not to provide exhaustive reviews of literature, but I think adding a citation or two would be valuable. There have been some updates (Gaynor et al. 2019), and research on the way in which human disturbance interacts with presence of natural predators. This latter point fits very well into the wolf/prey landscape of Wisconsin.

Page 110: Throughout the report, the maps prompted me to think about various analyses that could be applied to the spatial patterns. I'd be surprised if people have not already begun thinking about spatial statistical methods to compare processes such as those depicted in Figs. 38 and 39. There are many examples of such analyses in ecology, including comparison of methods such as nearest neighbor, Ripley's K, spatial point correlations, etc. (e.g., Perry et al. 2006). After "heat maps" of prey mortality locations and predator movement frequency (from telemetry) kernel methods can be used to compare the correlation between the processes. You cite the maps that compare locations of wolf harvest from the 2021 season with depredation locations, but that only scratches the surface of the spatial analyses that could be undertaken.

Page 135: regarding Objective E5c, I might have missed it but has someone built resource selection functions for Wisconsin wolves and compared them to data from elsewhere? I know there are RSF analyses from Yellowstone, Ontario, and probably elsewhere.

The maps of pack territories and those of the proposed management zones made me wonder if there have been analyses of dispersal corridors. Has there been an analysis of marked individuals from 1 and 2 into 5? Or the frequency that individuals from 1, 2, and 5 disperse into 3,4?

And given the regional nature of the DPS, what about genetic analyses of founders of the Wisconsin population? Or a landscape-level analyses of corridors across the region? This point transitions to the next topic of population genetics.

Theme 3: Population Genetics

Though I am not a population geneticist by training, during the last 20 years I have collaborated on landscape genetics projects on carnivores (bobcat and gray fox). Both projects provided important information to the conservation of those species. In fact, my colleague Dawn Reding and I are continuing research on bobcats in the Midwest, hopefully to include Wisconsin sampling. In our justification for cooperation by the various states we have noted the continuing changes in distribution of bobcats in the region, including whether populations will persist in agricultural landscapes, or whether cryptic boundaries between subpopulations influence population viability, and whether there is potential for local adaptation to climate change (Reding et al 2012). Answers to the research questions will enhance genetics-informed conservation management.

I bring this to your attention because it a similar justification applies to future management of wolves in the regional landscape. As further evidence of such thinking, the state of California suspended almost all hunting and trapping of furbearers. The state commissioned (and funded) the California Conservation Genomics Project (CCGP), an initiative with a single broad goal: "to produce the most comprehensive, multispecies, genomic dataset ever assembled to help manage regional biodiversity." https://www.ccgproject.org/about-us. In the future, it seems likely that the public may expect population data that applies throughout the ecosystem and at regional scales. State and federal agencies will be challenged to meet that expectation, without specific regard to jurisdictional boundaries. Effectively, management of the Great Lakes DPS of wolves is already at that point. Schweizer et al. (2016) has explored the conservation implications of local adaptation by wolves. And the genetic studies called for by the Draft Plan has the potential to provide the most important information about population structure and linkage that applies not only within Wisconsin but across the region.

Theme 4: TEK views

The Draft Plan is reasonably inclusive of Indigenous viewpoints, giving the tribes the opportunity to express their cultural beliefs of the kinship relationship with wolves and the importance of maintaining ecological integrity and diversity. In contrast to the details of the Draft Plan, which are rooted in the conventional North American Model (NAM) of wildlife management, the tribes express the view that wolves don't need to be managed but respected and conserved. The two views might seem diametrically opposed. However, acknowledging that a similar "natural regulation and integrity" viewpoint has been explicitly recommended by scientists who have prominently contributed to conventional wildlife management. I would cite the A. Starker Leopold et al. (1963) report that specifically recommended the natural regulation policies for Yellowstone, and which ultimately laid the foundation for the reintroduction of wolves to the ecosystem. I would acknowledge that The Wildlife Society itself has recognized that NAM has limitations and can be improved (Organ et al. 2012), responding to critics who describe it as too narrowly defined (or traditionally limited) (e.g. Serfass et al.2018). This suggestion might seem to undermine the overall acceptance of the Draft Plan, but I think it might reduce criticism that the plan is not inclusive enough of other viewpoints and values.

Page 123: although the definition at the beginning of Objective C may be intended almost as a legal statement, I the Draft Plan should encourage explicit inclusion of indigenous values as part of the defining statement. It is certainly true that "all wildlife including wolves, is held in esteem by tribal culture for the 'benefit' (probably not the culturally correct word) of present and future generations."

Page 138: under Objective F2a, what about an explicit recommendation for a study of management outcomes as perceived through TEK and conventional wildlife science, jointly funded by WDNR and GLIFWC? (see Moller et al. 2004)

Some specifics:
USFWS 2020b is listed twice in citations

Page 53: in the carrying capacity paragraph, the use of the work "predications" struck me as odd, compared to "predictions"

Fuller et al 2020 is missing, or year is incorrect

It looks like a page number of 140 is incorrectly inserted after page 135, check page numbering

To the DNR
Wolf Plan Comments!

ONE QUESTION FOR ALL: What wildlife is MUCH MORE important in Wisconsin?!?! DEFINITELY NOT wolves! SURELY White tail deer!! FOR ALL people to observe! For well managed hunting, AND important ~~food~~ FOR HUMANS!!

~~300~~ YES, OK 350 wolves MAX for their existence AND healthy survival — NOT MORE so they have plenty to eat. NOT MORE so we people have plenty of deer to enjoy observing, and hunting, and eating!!

LISTEN to the VAST majority of us citizens who provide the VAST majority of resources unto the preservation of a healthy deer herd that we ALL enjoy seeing on our landscape! How often does Anyone see a wolf?!

Let's firmly establish a solid plan for including a MAX of 350 wolves, for the harmony of wolf and deer!!! And PEOPLE!!

Sincerely,
Tyler Conrad [redacted], Oshkosh 54901

to DNR

Wolf Mgt Plan Comments
PO Box 7921
Madison WI 53707-7921

My purpose here is to encourage predator protection, a ban on recreational killing of wolves, and instituting non-lethal conflict practices for predators.

Beyond the intrinsic value of wildlife as a sign of healthy habitat, humane and animal, protecting predators is good wildlife management. Legal killing ultimately begets illegal killing, which benefits no one and is costly to all parties involved. There is public value in wise resource management practices. Thank you.

all best,
Craig J. Corsini

To whom in may concern.

I find 3 major flaws in the wolf managment Plan you are currently proposing

1. No Cap # or population goal 69 counties and 36 county boards have voted on 350 population cap. The counties in question need to be heard.
2. allowing a sovereign nation control over private property rights and not allowing leathal control when needed.
3. the current plan has no triggers for population control.

Therefore I most ask that these issues Be adressed.

Thank you
Daniel K Cuhutch
[redacted]

February 23, 2023

Adam Payne, Secretary
Wisconsin Department of Natural Resources
101 S. Webster Street PO Box 7921 Madison, WI 53707-7921

Re: Draft Wisconsin Wolf Management Plan

Dear Mr. Payne:

I am submitting the following comments on the Draft Wisconsin Wolf Management Plan as a life-long Wisconsin resident. I was born into a wolf-less Wisconsin, and have a profound cultural and ecological interest in their recovery in the state. Until retiring in 2022, I worked as a wildlife biologist for the Great Lakes Indian Fish and Wildlife Commission for over 35 years, and was the primary wolf biologist for GLIFWC over that period. In that capacity I served for many years on DNR wolf science, advisory, and roundtable groups in Wisconsin and Minnesota, and as an alternate in Michigan. I remain very involved in wolf stewardship today, serving through Wisconsin's Green Fired (WGF), and as a board member of both the Timber Wolf Alliance and the International Wolf Center.

The WDNR is to be commended for the significant effort they put into the preparation for, and production of, this draft. The existing state wolf management plan is nearly a quarter-century old, and much has changed on the land, and in our understanding of wolves and their role and function in Wisconsin's ecosystems. The draft plan successfully incorporates many of these new understandings.

Some of the particularly important improvements in the draft include:

- Adoption of a non-numeric population goal
- Greater recognition of the ecological benefits of wolves
- The proposed low-harvest zones around tribal reservations
- The use of zone-specific harvest permits
- Conducting and utilizing data from the social survey

The Department will undoubtedly receive push-back against some of these critical improvements, but I applaud the state for bringing wolf stewardship in the state into the present by including these factors, and making certain they remain components of the final plan.

There are, however, a number of areas where the draft plan can and should be strengthened before it is finalized. These include:

1) The General Use of Language in the Draft: Title: It's encouraging that the words "stewardship" and "conservation" are used in the plan's subtitle. However, within the text, the words stewardship, conservation, and management appear 22, 90, and 439 times respectively. Thus, management is used approximately 20 times more often than stewardship. The overall tone of the document would be improved, and would better represent the interests of the general Wisconsin public, if this was better balanced. (I would note that none of the 3 words appears in the department's mission statement, but

that statement begins with "*To protect and enhance",* a phrase that aligns more closely with stewardship and conservation than management.)

2) The Need for Separate Science and Stakeholder Committees: Wolf stewardship remains notoriously controversial and subject to political influences. It also a species of particular sensitivity to tribal interests. The collapse of the historical Science and Stakeholder Committees into a single Advisory Committee resulted in a loss of transparency and inclusivity, as a number of important stakeholder organizations became excluded from participating in the process, and the recommendations based on the best science became diluted by non-professionals before they ever left committee. It is imperative to restore separate committees to back the Department's commitments to both science and inclusivity.

3) The Stewardship of Ma'iingan in Zones 3 & 4: The state has indicated a likely intent to reduce the density of wolves in zones 3 & 4. There is no need for this, and it would undercut the ecological benefits wolves provide in these zones. The benefits of wolves are positively correlated with their number and density on the land. Density in these zones is naturally lower than in zones 1 and 2 because of somewhat poorer and more fragmented habitat. Yet these wolves may have a critical role in preventing expansion of CWD in the state, and further encroachment into the ceded territory. Weakening this likely defense can put tribal and non-tribal interests at risk. For the tribes, it is an issue both in the ceded territory, and in some cases, on-reservation, particularly for the LCO and the Menominee/Stockbridge Tribes, whose reservations are very close to these zones.

4) Other Zone Issues: a) There is an area on the east end of the proposed zone 3 that is very high quality wolf habitat, comprised of western Lincoln County and eastern Taylor and southeastern Price. This area was one of the first re-colonized in the state, and was previously included in Zone 2. There is no justification for moving this area to zone 3. I support the correction advanced by WGF that this area be included with Zone 1, having a western boundary consisting of Roads, Co. C, WI 102, WI 86, & Co. D (eastern Taylor and southeast Price Counties), southern boundary of US 64, and eastern boundary of U.S. 51.

b) I strongly encourage the state to note in the plan that they have the ability and may utilize temporary, small-scale, local harvest/research/surveillance zones may be established around newly documented Chronic Wasting Disease (CWD) outbreaks within wolf range. Within these temporary Wolf/CWD surveillance zones, wolf harvest should be kept to a minimum in order to maximize the opportunity for wolves to potentially control CWD expansion.

As noted by WGF and others, these temporary Wolf/CWD surveillance zones would also be focus areas for intensive surveillance and research, to document relationships between wolves, deer, and CWD.

5) The Lack of Public/Private Harvest Permits: Although subzones 1A and 4A (if adopted) may be able to shift some wolf harvest to private land areas, they are likely to be highly inadequate to distribute wolf kill appropriately between public and private land. This problem was grossly evident in the Feb 2021 kill, when 80% of the kill in the ceded territory was reportedly taken from the public lands which comprise only 28% of the ceded territory. This tremendously disproportionate take not only hit ma'iingan living in the best habitat hardest, but it robs the tribes of the benefits wolves provide on the very land where their rights can be exercised, and represents significant mis-management of the species. The only certain way to prevent a disproportionate harvest from occurring again would be to have harvest permits be designated for use on public and private land. With that tool, harvest could be distributed

proportionately, or shifted modestly away from public lands. I believe failure to effectively address the disproportionate take from public land may lead the tribes to seek legal remedies. It would be far better for state/tribal relations for the state to avoid that path.

6) Recognition of Tribal Rights: The plan makes some important and welcome improvements in recognizing tribal *perspectives*, but does less so in recognizing tribal *rights*. While this document cannot be expected to try to define tribal rights, it should recognize their existence by making a public commitment to making a sincere effort to develop a stewardship stipulation between the state and the tribes, as exists for other species such as deer and walleye.

7) Harvest Permit Levels: The draft recognizes the problems which occurred in the February 2021 season when harvest permits were set at a 20:1 level. However, problems also exist when permit levels are set too low. This may be more of an issue to monitor after the plan is approved, but the ratio should be set high enough to ensure that the season does not typically extend into February, which is detrimental to both pack stability and recruitment, and to the collection of sound and defensible population data.

8) Dog Training Proposal: The current proposal is to have the dog training period end in all zones when the final zone closes to harvest. The training period should end in each zone as it closes, both for the benefit of wolves, and for law enforcement purposes, as well as to reduce disruptions to the collection of population data.

9) Use of the Occupancy Model and Harvest Models Used in Setting Harvest Quotas: The discussion of these topics in the plan should be expanded to note some important issues. It contends that the Adams Harvest Model has worked better than the Fuller Model, but the difference is small, and the difference may not even exist if the analysis were extended to include the February 2021 season, which should be included in the analysis. In addition, both models have been tested under conditions where the population figure was based on a minimum count, not the "most likely value" generated under the Occupancy Model.

There is great uncertainty about population estimates generated under the OM, especially at the zone level. As a result, basing harvest quotas on the "most likely value" generated by the OM creates a significant risk of over-harvest, and a resulting loss of the ecological benefits wolves provide. As is done with tribal fishery harvests, quotas should be determined using the lower 95% confidence level of the OM, not the most likely value.

10) Research Needs: This section should include a goal of developing a metric using pack size to gauge wolf population health. Small packs likely have poorer recruitment, and Wisconsin is especially sensitive to this because average pack sizes are small under normal conditions. In addition, reductions in pack size have been associated with high levels of harvest. This is likely the most sensitive and most variable metric which biologists could work to define, but it will require a commitment to gathering adequate data annually by zone.

The above point are my primary suggestions for improvement of the draft. Following my signature are a number of additional points ranging from minor edits to fairly significant suggestions. I appreciate the effort that Department Staff have put into this plan, and the task of making further revisions, but if the past is any indication, this plan, once adopted, may be largely unchanged for a significant period of time. As a result, the Wisconsin public is best served by making the document as good as possible at this time.

Thank you for your consideration of these comments, and for all you do on behalf of our natural world.

Sincerely,

Peter David

Retired GLIFWC Wildlife Biologist, and GLIFWC Rep. to WI Wolf Plan Advisory Committee

CC: Randy Johnson, WDNR

Eric Lobner, WDNR

Additional Comments on Draft WI 2022 Wolf Plan

Page iv.

I commend the Department for including the language in Objective A regarding fulfillment of wolves' ecological role.

Page 3.

The line referencing Figure 3 mentions the line of 20 N Latitude; this line should be included in Figure 3.

Page 6.

The second paragraph is particularly nicely written.

Paragraph 4 should also cite the increase in beaver population associated with wolf recovery in Yellowstone to show the complexity of that relationship, and that wolves can have positive impacts on prey numbers as well. In addition, the more recent review of wolf/beaver interactions (Gable et. al, 2018 *The forgotten prey of an iconic predator: a review of interactions between grey wolves Canis lupus and beavers Castor spp*.) concluded that "The effects of wolf predation on beaver population dynamics are poorly understood, as most assessments are lacking in quantitative rigor and are instead based on indirect methods (e.g. scat analysis), anecdotal evidence, or speculation. To understand the effect of predation on beaver populations fully, better estimates (e.g. from documented predation events) of wolf predation on beavers are necessary."

Page 7.

At the end of the 1st (partial) paragraph, it could be added that wolf suppression of coyote populations may reduce fawn mortality by coyotes.

For Table 3, it would be helpful to include the elk population estimate each year. Knowing the % of Total Mortality that wolves cause is less informative than knowing the overall rate of mortality on the population. Higher mortality rates in the northern herd may be related to poorer habitat quality.

Page 8

The sidebar language should note possible differences in habitat quality between the 2 ranges, and that factors in addition to the loss of heterozygosity and predation, also likely contribute to slow growth of the northern herd. This section also highlights an issue that exists in several parts of the draft relating to the use of language appropriate to the audience. Generally, the plan does a good job having language the average reader can understand, which is great and consistent with the importance of this document as an educational tool. But some language here, such as the use of the term heterozygosity, should be simplified for a general audience. (The word "grown" in the first paragraph should also be "growth".)

This sidebar also seems to end with a potentially misleading statement that the "central herd has shown 15% average annual growth in its first five years (Figure 5)." I assume the growth from 216-2017 was due to additional animals being released, not recruitment, thus there are only 3 years of actual growth shown. In addition, most of the growth is attributable to a single year (2019 to 2020) so this is a very small sample from which to draw conclusions. This data should also be updated to include at least 2 more years of information which is now available.

Page 10.

In the first paragraph, it is unclear what is mean by "highly developed and *adaptable* social structure". This term could be eliminated, refined or clarified. Recent work also suggests that the breeding female likely really leads the pack, more so than the breeding male.

The language in this paragraph regarding lone wolves should also be clarified. Lone wolves are not considered "to be their own pack" under the DNR's population model (as noted later in the paragraph where it is noted that Wisconsin packs range from 2-12). It also worth clarifying for the reader that "lone" status is most often a temporary, not a life-long, condition.

The citation of average pack size is unnecessarily outdated. More recent DNR data (from 2012-2022) indicated an average pack size of about 3.7. While not a big difference from the older estimate, it is more current and likely reflects both the impacts of some hunting seasons and the expansion of the population into areas of lower quality. In addition, this actual data contrasts with the statement that established populations tend to have larger pack sizes, as the WI population is certainly more established now that it was prior to the 2009 paper.

The discussion on territory size should also mention that estimates of average size also vary with how they are estimated; average estimated size in WI has increased in part due to changes in method (such as the increased use of GPS collars). It should be noted that current estimates are primarily based on GPS collars.

Page 11.

In the Reproduction Section, I suggest inserting the word "fairly" in front of "high reproductive potential". While wolves do have fairly high potential, it is actually lower than for many animals, due to the limitation of one breeding cycle per year, and that fact that usually only one litter is produced per pack, so not all sexually mature animals typically breed. You should also clarify for your readers (who may not be familiar with wolf biology) that reports of multiple litters are not due to the lead breeder having multiple litters, but to a pack (in rare cases) having more than one breeding female. (The average

pack size in WI can be deleted from the () as it is already given in the text.) The mention of dispersal at the end of this section should be eliminated as dispersal only reduces the population if the animal leaves the state, which happens only at low levels and is likely relatively balanced by animals entering the state.

Page 12. The sentence "*Wolves' ability to disperse long distances allows for populations to readily expand and recolonize vacant habitats as long as human-caused mortality is sustainable (e.g., Mech 1995, Boyd and Pletcher 1999, Treves et al. 2009, Mech 2017, Hendricks et al. 2019)"* is generally misleading to the public, even if technically true. In fact, history in the Midwest and elsewhere clearly shows that in most cases wolves do not readily expand and recolonize, in large part because in the very areas where recolonization is necessary, dispersal tends to be dangerous and human-caused mortality is routinely high. Recovery in Wisconsin took decades, even under the protections of the ESA.

In the Mortality section, the second sentence (…*a variety of ways that a wolf can be killed*) should be modified, perhaps to read "… *many causes of mortality in wolf populations*", since some of the forms discussed such as starvation do not involve killing. In the next sentence, *"as well as in the past*" should read "and since colonization". The use of intraspecific and interspecific could easily be avoided here for the general reader ("wolves are also sometimes killed by the species they hunt, or kill each other, with the latter being more common in instances of low prey availability", for example).

In the first sentence of the last paragraph on the page, "a degree of" should be inserted in front of the word "resiliency"; as it reads now it suggests packs are not affected, when in fact they often, if not always, are to a degree or for a period of time. Also, again "fairly" should be inserted before "high reproductive potential", as earlier. In the same vein, the word "quickly" should be deleted in the same sentence; it appears that Wisconsin's wolf population is going to take at least 2 years to rebound from the Feb 2021 wolf kill, a length of time most people would not consider "quick".

This section would also be an appropriate place to discuss typical life spans for wolves, which is absent from the document.

Page 13.

The discussion of trophic cascades should also note that this is a difficult concept to study, and research is ongoing.

The side bar on ecosystems services should be expanded to include additional items noted since the Licht paper. The first item listed is perhaps the least strongly supported; the list also fails to mention the likely benefits of disease control in prey populations (the Isle Royale moose study, for example).

Page 14.

In the second paragraph, the meaning of "visitation" may be unclear to many readers.

Page 16.

The discussion and citations in the CWD discussion should include the findings of Tanner et al., (2019) who found that by selective predation, in northern Spain, there is a much lower level of tuberculosis in wild boars where wolves are present, and there is also less transmission of this TB to livestock. At the end of this section (on page 17), I recommend adding the sentence "However, until a full understanding

of the ability of wolves to limit CWD is available, a conservative approach towards the stewardship of both deer and wolves would be to assume benefits exist."

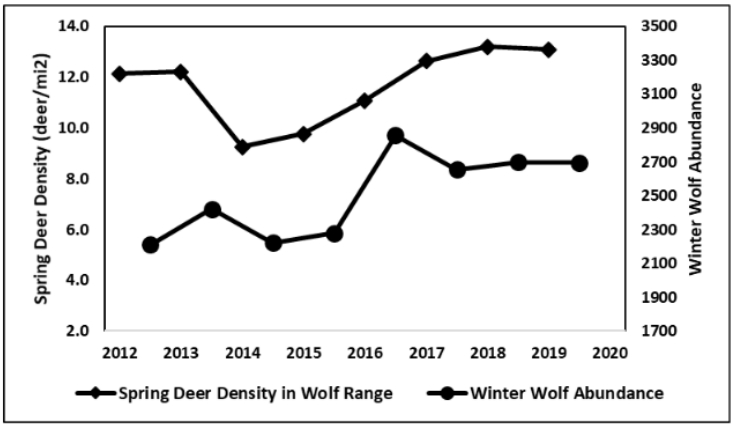
Page 17.

The section on Predator-Prey dynamics would benefit by the addition of a side bar that explains compensatory vs additive mortality and carrying capacity in a bit more detail for the public, as these are fairly complex and important topics.

This section could also note the increase in beaver in Yellowstone following wolf recovery, and reiterate the previously noted higher survival of pronghorn in wolf areas.

This section should also include data on deer/wolf population trends available for WI and MN. For example, wolf abundance in MN has been positively related to deer abundance (fig. from the MnDNR):

From spring 2018 to spring 2019, overall average deer density within wolf range remained stable. Over the past 8 years, the trend in winter wolf population size has been positively correlated with average deer density within wolf range the preceding spring (Figure 6).



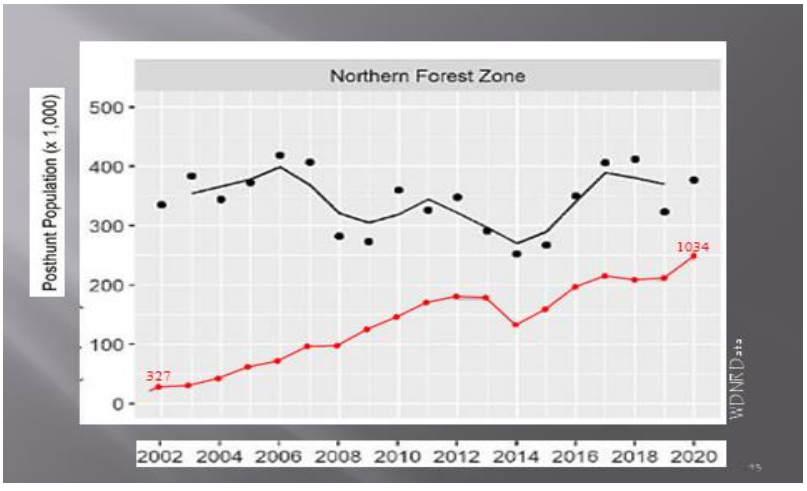


Figure 6. Comparison of estimated spring (pre-fawn) deer density and winter wolf abundance in Minnesota, 2012-2019.

And WDNR Data from the northern forest zone could be shown with trends in deer numbers, where there has been little trend in deer numbers even while the wolf population tripled: (Wolf numbers in red, scale not shown).

MI DNR also put out an extensive report on factors limiting deer in the UP, that included a primary summary finding was that "when deer numbers decline, it is not because wolf numbers have increased and when deer numbers increase, it is not because wolf numbers have declined."

This is all important and local information and should be included as this topic is a primary public concern.

Page 19.

“Off-take” is again a term that needs to be defined for the public.

There is a good discussion of the cautions to be applied to some harvest studies, but it should also be noted that many/most studies were also of relatively small areas. Changes in immigration/emigration rates are not very significant at a state level, as most movements will remain within the state population.

Page 20.

The biological meaning of the term “fitness” is again likely unfamiliar to many readers.

This section should also discuss the importance of the timing of the harvest. The killing of wolves in February, for example, is more likely to result in disruptions to recruitment than mortality in November.

Page 21.

In the second last paragraph, the word “face” should be replaced, perhaps with “cause”.

The conclusion of Stenglein is an important one that is consistent with wolf biology and should be emphasized somewhere in this documents: that wolf populations are highly self-regulatory and tend to roughly stabilize at low levels relative to other wildlife species.

And the conclusion that “wolf populations are remarkably resilient to human-caused mortality” should at least be modified by changing the word “are” to “can be”, as the extirpation of wolves across most of the lower 48 was also due to human-caused mortality.

Page 23.

I understand this is a verbatim inclusion of a paper, but it is unfortunate that the paper reads “…*the U.S. Fish and Wildlife Service has removed wolves from the federal endangered species list and placed them under state management at several points”*, disregarding the fact that management authority also passes to the tribes at these times. This should be corrected with a footnote in the current document.

In a similar vein, it is unfortunate that the paper chose to discuss “tolerance” for wolves, rather than acceptance. While the meanings are similar, this word choice is laden with cultural overtones.

This paper also makes some curious representations of some findings. For example, in discussing the recent MN wolf attitude survey, it states that 69% of the general public held positive attitudes toward wolves; by itself this tends to imply that 31% held negative attitudes, but in fact only 20% held negative attitudes, and the remainder were neutral. It also notes that 51% were neutral or supportive of a wolf hunting season, suggesting overall modest support. However, in detail, 48.9% opposed a hunt, 40.5%

supported, and 10.5% were neutral. These examples of slanted representations put the balance of the document into question. It is likely better included as an appendix than in the document itself.

Page 29.

There is a typo in the first paragraph; the word “and” after “wildlife program” should be deleted.

Page 30.

Under 2, it is noted that the 2014 minimum overwinter count was 660 wolves. This is true, but that information was not out at the time individuals responded to the survey. The most recent figure that was available at that time was from 2013, when the population exceeded 800 wolves. Thus for those knowledgeable about the wolf population, this would have been the number they were considering when they indicated if they wanted more or less then were estimated to occur, not 660. The clause about the 2104 count should deleted and replaced with “the most recent population estimate available when the survey was conducted was approximately 800 wolves.”

Pages 38-44.

Tribal Section: The inclusion of this material and the links to tribal ma’iingan documents is welcomed; it would be appreciated if these plans would also be included in the literature cited section.

Page 45.

The citation “David, 2009” is not included in the citations list.

Page 48.

The third sentence under the Population Growth Patterns should avoid the jargon “negative human interactions” and replace it with “intentional and accidental killing by humans”.

Pages 49 and 50.

I anticipate the text and figure describing the population will now be updated with data from 2022, particularly since this is the first count that reflects the impact of the February 2021 season.

Pages 53-54.

It will be a challenge, but it would be nice to make the discussion of biological carrying capacity more appropriate for the general public. Van Deelen’s work already is a bit outdated by actual population growth, and could perhaps be deleted or covered more briefly.

Page 55.

The last sentence in the paragraph at the top of the page should clearly state that the 350 figure was not a cap on the population. Given all the efforts to mis-represent this figure over the years, this document should make its meaning clear.

Page 60.

The last sentence in the caption for Figure 17 should be edited to read “Through the treaties, specific Ojibwe tribes reserved various off-reservation usufructory (use) rights, including the right to hunt, fish, and gather on certain lands and waters within the Ceded Territory.”

Page 64.

The citation to Wydeven et al. 2009b in the first paragraph of the 1979-2020 section should be moved to after the word “project” earlier in the sentence, since a paper published in 2009 cannot show that the project has continued to the present.

Page 65.

In the third paragraph in the 2020 to Present section, I suggest adding a sentence after “The final estimate also accounts for the uncertainty in all model parameters, including mean home range size and pack size” that reads “As a result, the occupancy model generates a range of numbers which the population likely falls between, rather than a single figure.”

Page 68-69.

It’s important to update the discussion of the quota setting process to include data since 2020. The results of the February 2021 season fall much more closely to the Fuller model to the Adams, enough so that the conclusion that Wi data has been better represented by the Adams model may no longer be true. In addition, you could explain why you have applied only these two models, and should explain the limitations of both models, including that they do not account for where the population is relative to K.

Page 71.

You should clarify for the reader why zone closures require a minimum of 24 hours public notice before going into effect.

Page 72.

There should be an * and footnote in Table 12 explaining why the age of the animals taken in the Feb. 2021 season differs so greatly from previous years, including mention both of the different timing of the harvest and the different method used to estimate age. Undoubtedly many of the animals listed as subadults were actually young of the year about 10 months old.

Page 74.

The second sentence in the Livestock section should be edited to read: “… wolf population grew and expanded, conflicts also increased, *until approximately 2010.*” The current sentence implies that depredations continued to grow the entire time the population grew, which is not true.

Page 75-77.

The section on Non-depredation Impacts on Livestock should clarify that much is unknown in this realm, and research is needed. Many of the citations discuss the impact of “predators” in general. As a result, it should be noted that the presence of wolves may reduce the possible negative impacts of other predators, especially coyotes. In addition, some of the citations used or arguments used are poorly

supported. For example, the Chebel et al (2004) paper discusses the impacts of exposing cattle to external heat stress (warm ambient temperatures), but it is used here in a discussion of animals warming from activity, a very different thing. This is a particularly unusual discussion – in that the study looked at the impact on artificial insemination, and the heat stressed discussed by the authors was from animals "defending their offspring from predators", something that occurs long after insemination. Similarly, the discussion about "dark cutters" cites a paper that is focused on the stress animals are exposed to in the process of going to slaughter; the link to wolf impacts is suspect at best.

Page 81.

I suggest inserting the word "hound" in the following sentence in the first paragraph: "In early wolf recolonization in Wisconsin, it was recommended that *hound* hunters avoid areas occupied by wolves." At the end of the same paragraph, suggest changing "occupied by wolves" to "within wolf territories", as most areas are not "occupied" most of the time.

Under the Human Safety and Risk Perceptions section, it could be noted there was a human injury in MN, involving a wolf with a deformed jaw. (I suspect this is the non-fatal USA attack included in Figure 28.)

Page 85.

The last paragraph under the Integrated Wolf Conflict Management Program should be expanded to include the recognized opportunities for active prevention efforts. These activities have been better funded in MN in recent years and MN Aphis reports that "In the two years that Minnesota Wildlife Services' conflict prevention program has existed, there has been no verified wolf damage inside turbo fladry-protected areas or where other non-lethal prevention activities have been deployed." (USDA-WILDLIFE SERVICES WOLF DAMAGE MANAGEMENT IN MINNESOTA 2021 Report)

Page 93.

Regarding heartworm, GLIFWC found much high levels of heartworm in the sample of animals taken in the Feb. 2021 season than has previously been reported for Wisconsin or neighboring states. I strongly encourage you contact GLIFWC regarding this finding.

Page 95.

The Other Concerns section should identify a potential new concern, arising from the recent MN studies which found widespread levels of neonicotinoid pesticides in deer in that state, with 64% of the neonicotinoid exposures reaching or exceeded the level considered a risk threshold for deer. Wolves might be expected to carry even higher levels, but have not yet been sampled.

Page 99.

Twice on this page it indicated the WAC would make "preliminary recommendations" to the department, when what is meant is that they would make recommendations for the department to consider.

When considering options for the wolf population in various zone (second paragraph discussion), taking no action (i.e. – allowing the population to trend naturally) should be a recognized option in addition to "increasing, maintaining or decreasing".

Page 102 (and elsewhere).

The state should work with its partners to identify metrics related to wolves fulfilling their ecological role; these could consist of things like maintaining certain wolf densities or distributions, maintaining certain levels of plant regeneration, etc. While the actual metrics will need to be identified later, the plan should commit to working on their development.

Relative to Objective B, it may be difficult to maintain downward trends in conflicts with hunting dogs if hound hunting and training grows substantially, by in-state or out of state hunters. The state needs to monitor the level of these activities more closely so that the level of conflict is better understood, and this metric should be expressed and measured relative to the number of participants.

Page 104.

This sentence should be edited as follows: "The purpose of wolf management zones is to allow management activities to be tailored on a regional basis to ultimately increase their effectiveness., ~~particularly given the disproportionate impact that wolves can have on those living within wolf range.~~

The clause to be deleted is unclear in meaning and unnecessary.

(I am sure you have already noticed that caption for Figure 34 is also erroneously duplicated on this page.)

Page 105.

I reiterate my concerns about potentially reducing wolf populations in zones 3 & 4. In the zone 6 discussion, the statement is made that "Individual packs have become established in pockets of more suitable habitat within this zone in the past and this is likely to continue." In fact, if wolves are delisted and your objective of high harvest in this zone is met, it is unlikely to continue, particularly since the areas of best habitat in this region are also the ones that provide the best hunting opportunities. Driving the existing population of wolves in this area to very low levels is contrary to the public's desire to maintain the existing distribution of wolves in the state.

Page 114.

The second sentence under Strategy A4 should be modified to read: "Over the years, the health monitoring component of the wolf program has included collection and analysis of biological samples from live-captured wolves, analysis of wolf scats, ~~and~~ necropsies of wolf carcasses*, and the collection of biological samples from hunter-killed wolves.*

Page 115.

The last sentence in the first partial paragraph should read "(whether real ~~and~~ *or* perceived)."

Under Product A5a, the Department should not be suggesting that "robust predator guilds" are an actual challenge to deer in Wisconsin; however, vehicle kills could be added to the list of challenges. This

paragraph should really be re-written to emphasize that Wisconsin has a very healthy deer population, and can be expected to continue to do so over the life of this plan.

Page 117.

First paragraph: as noted previously, it may be unreasonable to have stable or declining numbers of dog depredations if the number of dogs on the landscape significantly increases. This metric should be based on a level of depredations relative to the number of dogs – and that will require monitoring of the number of people hunting with and training hounds in the state.

Page 118.

Product B1f: The approach outlined to meet this product are likely highly inadequate to actually direct harvest towards areas of conflict. The use of specific public and private land harvest permits are much more likely to be successful in this regard. The state should also develop a metric to measure how will this product is being achieved.

Page 120.

Product B3d: The data discussed in this section should also be shared in a transparent and timely way with tribal governments and their agents.

Page 123.

In the first paragraph under Product C1a: the following line should be edited, as in many cases it is not necessary to manage wolf abundance at a landscape scale: "This season will offer the interested public an opportunity to legally harvest wolves, provide the primary mechanism to manage wolf abundance and distribution at the landscape scale *if and when necessary*, and can do so without …"

Page 126.

Product C2e: See concern listed earlier about need to have separate Science and Stakeholder committees.

Product C2g: See concern listed earlier about issuing enough permits to prevent seasons from extending into the breeding season.

Page 127.

Product C2h: See concern listed earlier about training season closure.

Page 132.

Product E1a: This section should specifically note the need to research the effectiveness of the occupancy model's performance under hunting conditions.

Page 136. (which somehow is marked page 140)

See concern earlier about the need for separate science and advisory committees. This step is one of the strongest the State could make to commit to its goal of science-based stewardship. The discussion in this section also fails to recognize the existence of separate committees at times in the past, instead implying that a single committee has always been used (*This committee has taken on various forms and*

functions over the years…). As noted earlier, a single committee in fact is less transparent and less inclusive. I applaud the Department for including unaffiliated individuals in the Stakeholder Committee, and the intent to convene the committee(s) at least annually regardless of wolves' legal status. However, the committee(s) should also have representation from academia, to help build trust in the process.

Jan. 4th 2023 Dear D.N.R.,

I'm writing with regards to the Wolf Management Plan, where I can comment on. To be honest, this should be a simple plan. I know the Wisconsin Wildlife Federation (WWF) filed many objections. In addition wanting a wolf population of 350, which isn't sciencced-based, in my opinion. I think a sweet-spot of roughly 500 wolves would be plenty, plus would help keep the population diverse. Inbreeding would be kept to a minimum.

To be honest, instead of a hunting season and tags are sold, how about a lottery? A lottery would be a better way to control how many wolves would be shot and would eliminate the issue that happened last time when there was an over harvest.

How about the farmers with livestock? Two plans come to mind. First, a tax break for farmers who spend money on non lethal ways to combat wolves. That be the purchase of dogs or donkeys to protect livestock. Or to add better fencing. Or to hire a farm-hand that watches over livestock. All three of these are effective and have been proven. Especially

specialized dogs, and the use of donkeys.

The second way to help farmers, offer special permit tags to take care of problematic wolves. A D.N.R. warden can come out to evaluate the situation, and issue a permit/license to that farmer as long as proof is shown. This permit can be issued anytime of the year.

For residents with acreage and close to a Native Reservation, the landowner should have a right to hunt on their property with the proper permits (as in license/tag etc.). A buffer zone around a Native Reservation should be solely for public or government land, not privately owned land. Maybe a minimum acreage, and away from any village or city. To be determined/set by the DNR.

One other issue that should be looked-at, is instead of a lottery and tags issued to any zone(s), maybe issue tags in zone specific areas where wolves are more problematic or concentrated to a specific zone. This way the wolves are thinned-out ~~an~~ in an zone ~~area~~ where there is a heavy ~~#~~ presence. Send the hunters to the areas/zones where hunting would be fruitful for the hunter, and beneficial to

the zone due to an over abundance of wolves. If there is a zone that lacks a strong wolf population, limit that zone.

As for the issue of just the average homeowner that lives in a village or city, or out in the country and loses a pet, maybe a type of tax-break to add a fence for their pet. Hate-to-say-it, but keep a better eye-out on their pet. If wolves are known in the area, be outside with your pet. Keep bear pepper spray on hand.

These are my opinions. And Thank You to the person(s) who raise these opinions to the committee.

Sincerely,
Ryan Dawson

To the Wolf Management Plan Draft Comments team:

Thank you for this opportunity. I am a long time resident of Wisconsin, and Illinois and Louisiana and North Carolina. I have always loved God's gift to us. A hunter will be a hunter, a hounder , hounder, wolf , wolf, turtle, turtle conservationist, and native alike, a leftist, and rightist.

Do we have to use wildlife, and natural resources to polarize ?

I once saw a police officer go off the road to kill a blandings turtle who's mate was trying to find it a block away. I saw approximately 5 dead wolves on the road this past year including 2 red wolves, and saw a hunter with a gun firing into the air to get it to run into traffic. I wonder if these wolves were counted as being killed. I am also seeing truckloads of trees coming down being transported to processing facilities who's wood from the previous year is sitting rotting in the rain and snow. I know good wood is not able to be replenished. Wood and furniture factories are having to use glue to put furniture together because they just cant get solid pieces. I saw a farmers cow get hit by lightning and its feet burnt off sitting in a field rotting. The wolf packs call is gone. I heard the last one cry and it was gone.

The bible says we MAN have been made responsible for the creatures and forests. The native Noah, Waynaboozhoo managed wildlife in his own way. He was respectful . ANIMALS DON'T VOTE HOLD A CHAIR OR POLITICALLY OPPOSE. THEY ARE OUR RESPONSIBILITY. The cow belongs to the farmer. The wolf belongs to the forest. Without the forest , and without lake superior running clean , we won't even have healthy soil, water, deer, forests or wildlife, or air. I lived in the South Chicago pestilence. BE GRATEFUL AND CONSERV. Do we need to manage? Of course we do . we need to manage all life including MAN. Everything from whales to ants.

Please people I am pleading with you to reconsider who your real enemies are.

Heres my list:

Awards to hounder's minimized and that incentive goes to farmers who feed us. It must be spent on electric fencing, or other deterents. By the way not all farmers feed us some feed oil companies. Incentive to put animals against animals is primitive it might be a tradition, but so is respect . I would only want to be a hound if I were loved.

Non lethal transport and lets think out of the box here packs would indeed be welcomed in other states where deer herds are out of control.

Science on the benefits to farmers who's livestock are close to wolf packs because of the way they kill off CWD infected deer, and more science on the wolfs natural immunity to many infectious diseases including CWD , and this SCIENTIFIC RESEARCH must not be conducted by entities trying to possess land

It must be conducted by real CONSERVATIONISTS who graduated from accredited schools of conservation.

DNR please send a letter to congress requesting the mandatory wolf hunt after delisting be removed from act 169

Enforce the law. Let the DNR do its job and the police do policing. Strengthen the DNR with more conservation, and real Science.

No hound training accept on private property out of wolf zones especially where wolf pups are present.

No use of bait and stronger penalties for poisoning,

8 hours to report a wolf kill, No nighttime hunting especially on other peoples land or around schools where I witnessed a guy hunting once. It was legal because he was in 100 yards lets change this.

Limit snowmobiles and ATVs

Include poached animals of all species

Good conservation science brought to the schools again.

Harder fines for poaching , and DNR members there to reinforce this. When I was a kid the DNR was on every lake. Now the only way to get ahold of them is down state online.

Count road killed , poached, and accidental wolf deaths and bear, and all species in the next years hunt count as a subtracted kill for the following year

MORE SCIENCE ON HOW THE DEATH OF A CREATURE AFFECTS THE PACK< and this goes for all living things. I once saw a guy shoot a mother beaver while all its babies were crying and screaming. He then left the site with her dead and all the babies sitting there in the middle of the river. Not to mention what type of negativity this exudes all over the universe.

No use of multiple snowmobiles, atvs and hounds this is not sport, this is slaughter. Lets create some boundaries.

We need boundaries. There are a lot of extinct species . this is the job of the DNR.

[redacted]

[redacted]

I am requesting my personal information not be used outside of this, however, the letter can be shared my information can be blocked out or whited out.

I am an advocate for women, and wildlife and the environment for the good of future children who might want to hunt, or just look, or listen. A wolf call cant only be heard but felt, a child's cry the same. Please help by doing whatever you can to hold on to what is left before it's all gone. I love trees. Seeing all of them especially the old ones being swept away all day long disturbs me. I am sure there is a place for them in the heavens. They are huge up there , and golden. We have a huge responsibility , we are in the last stages of resuscitating our home planet. Although science is guiding us to other planets recently I consider this to be home. I don't want to be buried anywhere else. We need it all. DON'T LET THEM DESTROY WHATS ON THE LAND TO CLAIM THE LAND. THIS DISPUTE REALY ISNT ABOUT WOLVES ITS ABOUT TERRITORY. Thank you . sincerely [redacted]

notes

I HAVE DEER HUNTED NORTH OF HWY 64 ON OUR PROPERTY FOR 46 YEARS. THE NUMBER OF DEER SIGHTING HAS STEADLY DROPPED.

HAVENT SEEN DEER TRACKS OR TAILS FOR ABOUT 4 YEARS, BUT HAVE SEEN WOLF TRACKS.

IT DOESNT TAKE A ROCKET SCIENTIST TO FIGURE WHY I HAVENT SEEN DEER AROUND

2.1.23

Dear Wisconsin DNR,

After reviewing your Wolf Management Plan I am concerned you are missing a population goal, are not setting up triggers for population management, and are giving a sovereign nation too much control.

I do not see a population goal stated nor a cap on the number of wolves in Wisconsin. 69 WI Counties and 36 WI County Boards have agreed to a 350 wolf population cap. I feel this plan is ignoring these groups' interests and goals. Please work with others in the state to achieve a plan that truly works for everyone.

I feel that your plan has no population triggers in place to initiate management techniques. Would it not be best to have a sound, clear plan that everyone can follow and that we can work towards a healthy wolf population but not have too many in the State?

Lastly this plan gives too much power to sovereign nations in my opinion. This plan does not allow lethal control when needed and the buffer strip affects private landowners.

Due to these three concerns above I ask you please review your plan, take into account everyone's thoughts and voices in Wisconsin, and then release a new plan for us sportsmen and citizens to further review.

Thank you for your time and efforts.

Sincerely,

James Downey

January 2 2023

To WI DNR;

I agree with the Wisconsin Wildlife Federation on their response to the 2022 Wolf Management Plan. Especially on items 13,14,19,20,21,22,24,26,27,32 of their response to the draft.

Also I feel strongly the people affected by the plan should have a larger say in the management of the wolf,and there should not be a buffer around reservation land.

When a species is reintroduced you have to have a plan to control the numbers. People living in the wolf range should have this say not someone without skin in the game.

Wolf Management Plan Comments
101 S. Webster Street
PO Box 7921
Madison, WI 53707-7921

RE: Please accept this document as public comment for the draft "Wisconsin Wolf Management Plan 2022".

I have read the entire draft, am a Wisconsin resident with a wolf ER license plate, attended all of the public WMPC meetings, have been a member of TWIN, took the WDNR wolf ecology and tracking course, and participated/commented on the 1999 draft "Wisconsin Wolf Management Plan".

Elements from the draft liked:

- The move to an adaptive culling model based on field and scientific data across 6 zones is progress beyond the endless interpretation battles over a number in the prior plan. The model is already being used for other Wisconsin species.
- Objectives A, B, D, E and F (Table 13) seem reasonable and balanced, although more about B, E and F later.
- Buffering tribal lands is a positive gesture to peoples who consider wolf as a relative. The buffer should be also a no-hunting zone.
- Objective E mentions a number of research areas to explore. I'd like to add:
    - research on pack dynamics and long-term affects when an alpha member is killed,
    - research on projecting global warming, land fragmentation and human population/migration effects on wolf ecology in Wisconsin,
    - research on non-hunter/trapper attitudes in hunted areas. I've seen questionnaire data on past hunts from the hunter/trapper communities but nothing from the rest of the communities impacted and
    - research on what is the carrying capacity of wolves in Wisconsin and what may be their potential population self-management.
- Objective F's Product F1a stakeholder group definitions for a WAC needs to explicitly mention the tribes, non-hunter and general public. I would add a diversity of women and people of color should also be encouraged. Referring to Figure 35, perhaps the composition of WAC should more reflect the 60-74% of the public who would like to see wolves occupy the same amount or more of Wisconsin.
- Objective F's Product F3f wolf summit is to be encouraged and if the pandemic has taught us anything, it's that our technology has matured to the point where all with internet access can participate. Open up summits to the interested public. This would support Strategy D1 efforts as well as potentially educate the hunters/trappers participating in seasonal questionnaires.

Elements from the draft disliked:

- Use of the euphemism "harvest". Flora is harvested; fauna is killed, culled, removed, relocated, hunted, etc. In the midst of the Holocene extinction, we need to be honest about what happens when there is a season on a species.

- Objective C is flawed in that there is no nutritional or fur value in a dead wolf. Basically a hunt is considered by some as a "sport" and by others something akin to medieval bear baiting, dog/cock/bull fighting or the like. The real issue is the occasional wolf or pack that gets into trouble from human contact. Activities in Objective B should address the specific human and wolf/pack at the time of an incident and not use some of Objective C activities to willy-nilly eliminate just any wolf over a multi-month period—a wolf/pack that was contributing to the social cohesion of a well-behaved pack. In other words, the innocent are sacrificed for "sport" or income from licensing. Research has found road density is not necessarily a limiting factor for suitable wolf habitat. What more are humans ignorant about wolf ecology?
- Of the 3 strategies and 14 products in Objective C, only 1 strategy with 2 products address the "stewardship" and "conservation" aspects mentioned in the draft's sub-title.
- Most vociferously I oppose Product C2h. Wisconsin—the only state permitting the hunting of wolves with dogs—should not be codifying a season of training for such an activity.
- Objective F Product F2e I would oppose. Why would hunters/trappers need to take a carcass out of the state, let alone the country. Trophy "sports"?

Rating on 1-10 scale of support for draft plan: (ie from very little to very high support)

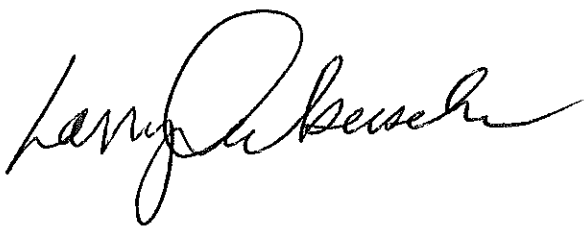
8.5

Other comments

- There simply must be action on getting the legislature out of the business of administrative rule making regarding wolves. The disastrous hunt of February 2021 in the wolf breeding season with a 24 hour gap between notice and zone closure for "sport" is not acceptable.

Thank you for reading these comments. I look forward to hearing about further developments of the plan.

Sincerely,



S B Duerkop

Feb. 13, 2023

I am writing to the DNR Wolf Committee expressing my concerns regarding the new proposed wolf plan. I live in northern WI in Rusk CO. where we have had many wolf encounters with family farms. I am also concerned for the safety of my lab dog when I enter our woods. She would not stand a chance with a pack of wolves. I do not believe that the DNR is giving us an honest number of wolves reported to be here in our state. Our state is deeply divided on this wolf issue.The southern metropolitan areas want wolves but has no skin in the game. There is no fear for their families, pets, or wildlife. We in the north cannot live the quiet peaceful life we had in the past. Farmers suffer animal losses. Hound hunters lose dogs and must avoid certain areas. Deer numbers are down considerably in areas which in turn causes business to suffer financially from lack of hunters. We have been affected in many ways and have little say in our prediciment. The DNR is managed and listens to the liberals in the south. We were promised only 350 wolves until we would have a controlled hunt. Now we have 3-4 times that amount and no planned hunt in sight. Two years ago 218 wolves were killed in 3-4 days. Doesn't that tell you we have a problem?? The Native Americans will never kill a wolf so why are they even factored into the projected wolf kill numbers? Why was the new wolf plan unvieled the day after the fall elections? What would it look like if we would have elected a Republican Governor or would it still be buried on someones desk? The whole wolf issue has gotten quite political and we know who controls it. Not the people who live up north. The DNR Wolf Planning Team did not even have the backbone to hold hearings in the northern part of the state to listen and get feedback from the people who live and deal with wolves on a daily basis. Incredible!! When the day comes when we have to reduce wolves in great numbers, will the DNR have the backbone to implement such a plan? This whole issue has not helped the credibility of the DNR!

Give us some numbers we can live with and support the people who have to deal with wolves daily.

Larry Dukerschein

Glen Flora, WI 54526

TO WHOM IT MAY CONCERN – OR NOT.

THIS COMMENT/COMPLAINT IS IN REFERENCE TO THE DNR'S UPCOMING WOLF "MISMANAGEMENT" PROPOSALS.

THE FOLLOWING WILL BE MY HUMBLE OPINION – NOT THAT IT COUNTS.

(1) YOUR INCLINATION TO NOW ABANDON YOUR INITIAL QUICK-SELL GOAL OF 350 ANIMALS IS BOTH DECEITFUL AND RIDICULOUS. PERHAPS YOU NOW BELIEVE THAT EVERYONE HAS BEEN MISLEAD AND BEATEN INTO COMPLACENCY WITH THE OVER-POPULATION OF WOLF NUMBERS. ANY SELF-REGULATION OF NUMBERS OR INCREASING OF SAME IS TOTALLY WITHOUT NECESSITY. KEEP YOUR PROMISE AND STICK TO YOUR ORIGINAL AGREEMENT.

(2) YOU ARE INCREASINGLY CREATING BAD POLICIES BY ALLOWING YOURSELVES TO BE INFLUENCED AND STEERED BY TOO MANY SPECIAL INTERESTS AND INDIVIDUALS DEMANDING ~~END~~ CONCESSIONS. THAT WOULD THE "WOLF CLUBS" AND THE TRIBES. LAST I KNEW THE STATE STILL HAD SOLE AUTHORITY, EVEN WITHIN THE CEDED AREAS, TO REGULATE. IF YOU CONTINUALLY WATER DOWN YOUR LEGISLATIVE RESPONSIBILITY SOON YOU WILL PRESIDE OVER NOTHING.

THE ENTIRE "WOLF THING" HAS BEEN A

MISERABLE DISSERVICE TO NORTHERN WISCONSIN GENERALLY AND SPECIFICALLY I'M REFERRING TO NORTHERN VILAS COUNTY. THE DNR'S RE-INTRODUCTION — OR RE-LOCATION AS YOU PREFER WAS A "SMASHING SUCCESS." THE COLLATERAL DAMAGE, HOWEVER HAS HAD OVER-WHELMING NEGATIVE IMPACTS. I WOULD LIKEN THE OPERATION GENERALLY TO YOUR RE-INTRODUCTION YEARS AGO OF THE FISHER. WE WERE OVERRUN WITH THEM ALSO UNTIL ALL OR MOST OF THE SMALL ANIMAL AND BIRD POPULATIONS COLLAPSED. THE SNOWSHOE HARE, RABBITS, SQUIRRELS, RACCOONS, GROUSE, AND SMALL BIRDS BECAME A RARITY. MOST STILL ARE. JUST ANOTHER "SMASHING SUCCESS STORY" IN THE NEGATIVE ASPECT. AS FOR THE DEER-WELL FORGET THEM — THE STATE/FEDS SHOULD POT THEM ON THE ENDANGERED LIST.

THE MENACING, MANGEY, FLEABAG WOLVES HAVE TOTALLY DESTROYED A WAY OF LIFE AND STRONG FAMILY TRADITIONS IN THIS AREA. ADRIAN "SLY" WYDEVEN'S PERSONAL DREAM AND CAREER AGENDA TO PUT A WOLF IN EVERYONE'S BACKYARD HAS PRETTY NEAR SUCCEEDED. SADLY HIS EFFORTS CREATED A HUGE PROBLEM FOR MANY PEOPLE AND THEIR BUSINESSES. EVEN MORE REGRETTABLY

HE WAS SANCTIONED BY THE DNR AND USED UNTOLD TAXPAYER DOLLARS TO DO IT. HIS PERSONAL INFLUENCE IS STILL DICTATING POLICY.
THE ENTIRE SITUATION IS JUST ANOTHER GOVERNMENTAL DISGRACE. THE DNR HAS FORSAKEN THE CITIZEN / TAXPAYERS WHO HAVE BEEN VICTIMIZED AND IN ACTUALITY YOU HAVE ALSO FORSAKEN THE WOLVES. BY CREATING CONTROVERSY AND RESENTMENT TOWARDS THEM.
IT IS WAY PAST TIME FOR THE DNR TO FINALLY MAKE THIS RIGHT AND THE ONLY WAY YOU CAN DO THAT IS TO SUBSTANTIALLY REDUCE THE WOLF POPULATION IN NORTHERN WISCONSIN.
PLEASE TAKE THE RESPONSIBILITY.

RESPECTFULLY,
MIKE DOWE

COMPENSATION, NOT KILLING

COMMENTS ON WISCONSIN WOLF MANAGEMENT PLAN 2022

(Wisconsin Department of Natural Resources. 2022. Wisconsin Wolf Management Plan. Wisconsin)

By

John F. Ebbott

Jefferson County, Wisconsin

January 23, 2023

I. COMMENDATION TO DNR

I have read every word of the 167 pages of the DNR Wolf Management Plan 2022. I would first like to commend the DNR on the comprehensiveness and detail of the information in the Plan. It reviews all conceivable aspects of wolf management, provides a plethora of valuable information, and reflects a great deal of hard work and thought invested by the DNR staff and advisors. I very much appreciate that the Department takes this subject so seriously and dedicates many resources to it.

That said, I do have some difficulties with the Plan and would like to see it amended.

II. OVERALL

My overall constructive criticism of the Plan is that, in attempting to balance the benefits of keeping wolves alive against the benefits of killing them, it undervalues the inherent worth of live wolves and overvalues the advisability of killing them.

The discussion of the benefits of wolves is less extensive than the discussion of the problems they pose to humans. There is glaringly little discussion of the economic benefits that wolves bring to Wisconsin. There is an endless recounting in "Wolf-Related Conflicts" (pp. 71-85) of quite speculative harm to livestock and dogs. The lack of injury and death to humans is severely understated. The pain and terror of death and maiming to shot and trapped wolves is completely ignored. Do they not feel pain, or experience fear? Do they not want to live?

In the first three of the six Objectives, killing – hunting and "lethal abatement" – is the primary tool for management. To be sure, other tools are discussed, but killing is primary.

Compensation for damages is far preferable to killing, and the Plan does contain a creditable discussion of compensation. I do appreciate the Department's emphasis on compensation throughout. What I don't understand is why $3,000,000 paid out in compensation does not move killing to a secondary or tertiary position. I say this with full understanding that the legislature has mandated wolf-killing, so the Department is required to allow some. But, as the Department itself acknowledges, its authority to maintain open and closed species seasons under sec. 29.014(1) Wis. Stats. is "broad". (p. 60).

I also, at this point, would note that "harvest" is a very misleading euphemism for painful death of wolves. We are not engaged in combining oats, or mowing hay, or picking corn, here, the traditional meaning of "harvest". Yet "harvest" is used pretty much everywhere in the Plan. It is as obscuring and euphemistic a term as "slaughter" would be inflaming and dramatic, which is why I will not use "slaughter" as a synonym for hunting, trapping and "lethal abatement". I will use "killing" throughout as the least euphemistic and inflammatory, and most realistic, descriptor of the death of wolves.

III. OBJECTIVE A

While **Objective A** is entitled "Ensure a Healthy and Sustainable Wolf Population to Fulfill its Ecological Role", it sets the very low numbers of 100, 200, or 250 wolves as the "thresholds that should not be approached". (p. 111). This, to use the benchmark of 200, would still permit the killing of 772 wolves, based on the 2022 population of 972. (p. 68). This is too many. These thresholds are far too low. A threshold of 1,000 is more reasonable.

In connection with this, another misleading term here is “population abundance”. (See p. 112, **Product A2a**). This leads the reader to understand that the wolf population is usually “abundant”, and thus can absorb some killing. The term “population scarcity” is never used. Why not?

A dangerous “product” in **Objective A** is **“Product A1e”**, the contracting of trappers to livetrap wolves. A livetrap can be placed next to a deathtrap, with the result that trappers are paid to trap wolves, sometimes alive, sometimes dead. GPS collar placement should be left to DNR staff, not given to persons with an interest in wolf pelts.

Killing wolves – “harvest” – is clearly contemplated as a “management action” in **Product A2a** (p. 113). Thus, killing is a given, as the Plan is to monitor how many wolves remain following the hunt.

Strategy A3 is generally quite good, especially the prevention of illegal killing, though it seems this prevention has not been particularly effective in the past. **Product A3c** (p. 113) is good as far as it goes, but investigative reports should be made available to the public when the investigation is finished – the ***reports***, not just annual summaries. Many of us would like to know what happened with illegal kills and what law enforcement did about them. Is there “effective law enforcement”? (**Strategy A3**, p. 113).

As to the purposeful destruction of occupied wolf dens (pp. 113-14), it is very difficult to accept the department’s assertion that, even though “only some fraction of dens received protection in the past”, (p. 113), nevertheless, “lack of protection among the rest of active dens appears not to have negatively affected the wolf population”. (p. 113). Seriously? How can it not? There is no explanation as to why this is so.

The Department should not hold out administrative rulemaking as a remedy for den destruction. This is a copout. The JCRAR will never approve such a rule. The Department should consider the purposeful destruction of occupied dens to be very likely to lead to the death of wolves, and thus to be illegal killing. No need for a rule.

Also, it should not matter that this places a "burden on those planning or conducting activities within wolf range". (p. 114). Those persons should just stay away from the dens, burden or not.

Product A4d's emphasis on maximizing animal welfare is good. (p. 114).

Strategy A5 is to maintain the deer population (p. 114). There is early and prominent recitation of the "high demand for recreational deer hunting". (p. 114). In fact it is set forth again and again: " . . . continued public expectation for quality deer hunting opportunities" (p. 115) and "public concerns regarding the impacts of wolves on white-tailed deer populations (whether real and [*sic*] perceived) will continue to require attention to maintain and/or improve public support for wolves". (Ibid.)

The DNR uses the term "public" too broadly, when it really means "deer hunters". This language raises the question whether "attention" includes killing many wolves so deer hunters have plenty of deer to shoot.

One question is why deer hunters are so concerned that wolves will kill so many deer there won't be any deer left. In 2022, the deer population is estimated at 1,554,400. Deer licenses sold were 795,072. Deer kills registered during the gun season were 203,295 – up 14.4% from 2021. In the Northern Forest, prime wolf range, 38,795 deer kills were registered. Wisconsin's "most likely" wolf

population is 2022 is 972, in 288 packs. To wipe out the deer herd, each wolf would have to kill 1600 deer. To wipe out the deer killed by hunters (203,295), each wolf would have to kill 209 deer. This is unlikely, especially since only some of the 972 wolves kill to feed the pack.

Wolves are hardly a threat to deer hunting. In fact, the 1,554,400 deer could support many more wolves. And this is without considering elk.

Wolves will self-limit their numbers if prey numbers are limited, so no wolf-killing season is even necessary. As the Department itself states with regard to elk: "Both elk management zones are likely near a saturation point with wolf packs and have been for some time, meaning w3olf numbers in elk zones ***are unlikely to change***". (p. 115; emphasis mine). Wolves will self-limit; there is no need for a hunt.

Strategies A6 and A6a are generally good, particularly the low road density recommendation.

IV. OBJECTIVE B

"Lethal abatement" (killing) plays too prominent a role in this objective, even though it is hedged with "where practical and appropriate". (p. 117). The discussion of compensation and preventive measures like fences is good, but compensation and prevention should be the first and greatest activities, with killing not even an option. **Objective B**'s concern with conflict is, unfortunately,

not balanced by an "Objective" to preserve wolf life for its own inherent moral and spiritual value.

Aldo Leopold eloquently expressed this value in his famous "Green Fire" quotation: *"We reached the old* wolf in time to watch a fierce green fire dying in her eyes . . . I thought that *because fewer wolves meant more deer, that no wolves would mean hunters' paradise. But after seeing the green fire die, I sensed that neither the wolf nor the mountain agreed with such a view."* Leopold, Aldo, *A Sand County Almanac, "Thinking Like a Mountain"* at 115.

There are a great many people in Wisconsin - members of that "public" of which the Department speaks – who share this value with Leopold, who want wolves to live because they are God's creatures, not for some merely utilitarian reason. There should be an "Objective" dedicated to this value, an "Objective" fully developed.

With regard to wolf/livestock "conflict": This concern is greatly overblown in the Plan, pp. 74-79. First, the Department acknowledges that "the total number of farms and livestock involved in wolf depredation and harassment incidents across Wisconsin are numerically low". (p. 74). There are ***very few*** wolf/livestock conflicts. But the Plan brushes off the fact that these rarely occur, and hurries into a speculative discussion of "non-depredation impacts". (Ibid.) Apparently, this is some kind of effect of wolves ***not depredating***, but it is their fault anyway.

This entire discussion seems biased against wolves. The alarmist phrase "tip of the iceberg" is used. One cube of the iceberg is, apparently, heat stress. (p. 76). A study (Chebel) is cited for the fact that heat stress prior to artificial insemination resulted in lowered conception rates in dairy cows. Another study (Garcia-Ispierto) showed that dairy cows exposed to high heat index values during peri-implantation ***may*** also have a greater risk of pregnancy loss. (p. 76). Apparently,

it's bad for dairy cows when it's too hot. But these studies do not appear to attribute cow overheating to wolves. If anything, these studies indicate that we should drastically reduce human-caused global warming, not wolves.

This entire section is replete with dubious causation terms – "may", "perhaps", "can", "likely", "possibly", "postulated". (p. 76).

Another strike against wolves is apparently herd overcrowding: "concentrating cattle in small areas can increase the risk of transmitting food borne pathogens . . . the stress of crowding". (Ibid.) If crowding is bad for cattle, then perhaps confined area feeding operations (CAFOs) should be eliminated along with wolves. The study authors "postulated" that cattle form in groups and are "more sinuous" in the presence of wolves was "likely" an anti-predator defense mechanism. (p. 76). Hardly definitive. Cattle also form groups in response to hay being brought to the pasture.

It also appears from this section that livestock-handling dogs don't stress cattle when they engage in activity similar to wolf "harassment" (p. 76), whatever that is, but wolves ***do*** stress them.

This section, which argues that there are wolf "non-depredation" adverse impacts on livestock, that is, that wolves harm livestock even when they're not "depredating", is a proofless and strenuous reach to come up with another justification for killing wolves – "lethal controls may be considered". (p. 77).

Product B1e is good in its focus on improving animal husbandry practices to prevent future conflicts. (p. 118).

It is an extremely bad idea to direct hunters and trappers to areas of "conflict", as does **Product B1f**. First of all, what is an "area of conflict", and how many hunters and trappers will DNR direct into that "area"? If one farm in a county has a "conflict", is the whole county the target? If the "area of conflict" is 3 square miles, will 100 hunters and trappers be directed into this area and be told they are limited to it? **Product B1f** needs to be eliminated.

The focus of **Product B1h** on non-lethal abatement is excellent. (p. 118).

Strategy B2's provision for wolf damage compensation is likewise excellent. With adequate compensation, there should be no reason for killing wolves.

In **Product B2a**, it seems that the Wisconsin Farm Bureau Federation should not be the sole farm group on the panel. The Wisconsin Farmers Union should also have a seat.

Product B2e states that " . . . in some cases, calves can be depredated by wolves with no evidence or detection of the depredation". (p. 119). Nonsense. It is difficult to see how anyone can conclude that there is depredation without evidence of depredation. Maybe this is discerned through a hunch, or a gut feeling. Even the worst criminals can't be convicted without evidence – but wolves can, apparently, and then they are killed.

Product B3b's hotlines for wolf complaint reporting, monitored seven days per week at taxpayer expense, are fine, but there should be a similar hotline for reporting illegal killing and deliberate den destruction.

Again with **Product B3d**, wolf investigation reports should be available to the public.

As to **Product B4a**, the legislature should fund nonlethal deterrents if it is going to mandate a hunt. This should not be on the shoulders of underfunded NGOs. We all know that if there is not enough funding for a program, it won't get done.

Strategy B6 is very good.

V. OBJECTIVE C

The professed "multiple benefits" do not seem very "multiple". This objective is dedicated substantially to hunting and trapping, even though it initially speaks of "stewardship". The very first benchmark is a hunt. The second benchmark is hunter satisfaction. (p. 123). In **Product C1b**, trappers are the only interest group at the table.

The first strategy, **Strategy C1**, provides for, in the Plan's language, a "well-regulated wolf harvest season". (p. 123). Remove the "harvest" euphemism, and this is still a wolf-killing hunt, which shouldn't exist. The majority in the legislature has required one, but the Department's Plan could still restrict the kill so that wolves' suffering and terror is minimized.

Section 29.185(1m) Wis. Stats. provides that: "In regulating wolf hunting and trapping, the department may limit the number of wolf hunters and trappers ***and the number of wolves that may be taken*** by issuing wolf harvesting licenses." (Emphasis mine). Section 29.185(5)(c) Wis. Stats. provides: "The department may close a wolf harvesting zone to both hunting and trapping of wolves if the department determines that the closure is necessary to effectively manage the state's wolf population."

Thus, the Department has the authority, and the discretion, to formulate a wolf management plan that exercises a protective stewardship of wolves by limiting the number to be killed through limiting the number of licenses and the period of time that the kill zones are open. It should to this by setting a very low permitted kill number.

I am aware that the legislature, most unfortunately, required that 6 dogs on each wolf be permitted, along with bait, and traps, and predator calls, so the Department cannot prohibit them. Their harm can be minimized by regulating the season in the above fashion.

If this Plan enthusiastically endorses wolf killing, as it does in its present form, it severely limits the Department's discretion to use the Plan to mitigate harm. We certainly do not want a repeat of the February 2021 kill. Such enthusiastic is found in **Product C1a**: ***"This season will offer the interested public an opportunity to legally harvest wolves, provide the primary mechanism to manage wolf abundance and distribution at the landscape scale, and can do so without jeopardizing the long-term sustainability of wolves in the state."*** (p. 123; emphasis mine). With this language, the Department forfeits any ability to use this Plan to protect wolves.

"The interested public" is a euphemism for that small group of people that want to kill wolves, including sicc'ing 6 dogs on one wolf. I, too, am a member of "the interested public", yet my wishes are not recognized here.

The "primary mechanism to manage wolf abundance and distribution" is death.

The assertion of nonjeopardy should be viewed with the 2021 season in mind. This mass slaughter is, oddly, completely and mystifyingly ignored in the Plan. Lest we forget, with a DNR maximum kill set at 119 wolves, hunters killed 216 in 3 days – 82% more than permitted. ***90% of the hunters used dogs.*** This killing was done during the breeding season, so several of the wolves killed had to be pregnant females. 46% of those killed were females. As one wolf NGO stated: "Remove one wolf, you're essentially destabilizing and killing the entire pack." For a full description of the effect on a pack of the death of the alpha wolf, *see* Carl Safina, *Beyond Words: What Animals Think and Feel*, especially "Part Two: Howls of Wolves", at 137-241. I note that this book is not in the bibliography for the Plan.

The Great Lakes Indian Fish and Wildlife Commission, a member of this Wolf Management Plan Committee (2021) described the 2021 hunt*: "This season trampled over the tribes' treaty rights, the Wisconsin public and professional wildlife stewardship. It will go down as a stark example of mismanagement, and the problems that can be expected when the state Legislature and the courts embrace special interest groups over the public as a whole."*

The 2021 season was forced by a lawsuit filed by "Hunter Nation", a Kansas, not a Wisconsin, organization.

Despite full knowledge of this disastrous mass slaughter, the Plan asserts that a hunt "will not jeopardiz[e] the long-term sustainability of wolves in the state." (p. 123) I do not find in the Plan any safeguard against a repeat of the 2021 "harvest". Why is the 2021 hunt not included in the discussions of "conflicts"?

In **Product C1b**, trappers have the only voice at the table. This excludes all other voices who may differ from trappers. The Plan says the course provides information on how to trap "humanely". There is nothing humane about trapping, so this is a dubious claim.

Product C1c seems to be a way to spend tax dollars to help wolf hunters hunt wolves better. I'd rather my tax dollars go elsewhere.

Regarding **Strategy C2**, I have discussed the state statute and the scope of the Department's authority above. **Product C2c** is good in making licenses valid only in the zone specified on the license, which I believe the statute requires.

Product C2e speaks of engaging with the Wolf Advisory Committee. It is not clear whether the Wolf Advisory Committee is the same as the Wolf Management Plan Committee. The latter is stacked with hunters, trappers and farmers, so can be expected to recommend high kill numbers. There is the Wisconsin Bear Hunters Association, the Wisconsin Bow Hunters Association, the Wisconsin Cattlemen's Association, the Wisconsin Chapter of Backcountry Hunters and Anglers, the Wisconsin Conservation Congress, the Wisconsin Farm Bureau Federation, the Wisconsin Farmers Union, and the Wisconsin Trappers Association – about 28% of the membership.

A very key product is **Product C2g**, the number of licenses. License-to-quota ratio should be 5:!, not 20:1. Hunter-trapper satisfaction should not be a factor in setting quotas. No doubt the hunters were quite satisfied with 216 kills in 3 days in 2021, but that was bad for the wolf population. To satisfy hunters and trappers, the quota will always be higher than it should be – Wisconsin still has fewer than 1,000 wolves – 972 – a very low number.

Product C2h is a terrible idea – it permits harassing and killing wolves with dogs in the guise of "training". It *is* good that the Department to a degree recognizes the importance of the late winter breeding season. The limits on baiting are also good.

Finally, way down in 3rd place, is **Strategy C3**, nonkilling activities. It is good that the Plan at least recognizes that something other than hunting and trapping has value. But, these considerations should not be limited to the utilitarian ones of recreation and tourism. Equally legitimate is the value of wolves' simple existence, as recognized in **Product C3b**.

In the midst of all of the studies cited in this Plan, **Products C3a and C3b** mention two areas *not* studied, which are important and should be studied. **Product C3a** states that an economic analysis of tourism dollar benefits of wolves has not been completed in Wisconsin. (p. 127). The Department should conduct one posthaste. How can the number of wolves to be killed be reasonably set when this important factor is omitted?

Product C3b states that the public interest in preserving natural cultural heritages for future generations are "relatively understudied". (p. 127). Again, how can this be ignored when setting a kill quota for wolves? The Plan seems quite dismissive of the lack of knowledge in these areas. The Department should study them and make them a part of this Plan.

The Plan states that the existence, cultural and bequest values will be given "due consideration" when making management decisions (p. 128), but without a mechanism or set of criteria, this is dubious.

VI. OBJECTIVE E

Objective E demonstrates the foregoing point. **Product E2b** is quite silent about existence, cultural and bequest values. It speaks only of money: Tourism, deer hunters, dog owners' spending, and local economies. Even those who wish merely to see wolves in the wild are called "driven" (p. 133), as though they suffer from some sort of compulsion.

Product E2c talks about wolves reducing land values. As the Plan recognizes, there is no evidence to support this. Perhaps values *increased* due to wolves. Despite this lack of evidence, the Plan seems ready to spend tax dollars to help landowners prove their point. The Department shouldn't, but if it has enough funds to do this, it definitely should allocate the funds necessary to study the dollar value of wolf tourism and bequest values. (p. 127).

Strategy E4 is very good; in fact, **Product E4a** should be the first strategy under **Objective E**, and the report should definitely include the February 2021 killing. (p. 134).

Re **Product E4b**, this is good, and should include the effect on a pack of the killing of its alpha. This has a cascading effect, to the detriment of other pack members, and should be given weight.

Product E4c values ***only*** the opinions of wolf hunters and trappers. (p. 134). They should not be the only ones with a voice, especially if they are going to opine on the propriety of their own behaviors and attitudes. People who don't hunt wolves might have opinions about those topics, but they are shut out. This is an example of DNR bias toward hunters.

Strategy E5 is good.

Products E5c and E5d (p. 135) seem the same, and could be consolidated.

VII. OBJECTIVE F

In the "Definition" paragraph, it is premature to consider wolves fully recovered, and to recommend moving on to ongoing management. (p. 140/136). Many of us would like to see further recovery, and are not satisfied with 972 wolves. Many of us would have said so in 2022, but for whatever reasons were unaware of the DNR survey. Since I missed the survey, I am recommending further recovery through the submission of these comments to the Plan.

In **Product F1a**, despite the nod to inclusivity (p. 140/136), the "Shareholder Group Definitions" again favor hunters, trappers and farmers (p. 137). There is a 2-to-1 ratio of hunter and farmer groups to wolf advocacy groups. (p. 137). There is the "At-Large, Unaffiliated Residents" group, but the example used there

is another hunting organization, Ducks Unlimited. (p. 137). How many residents protective of wolves will be named?

Product F1c contemplates the Wolf Advisory Committee meeting once a year, albeit that is a minimum. (p. 138). The Committee cannot be at all effective if it meets but once a year.

The remainder of **Strategy F2** is good, particularly the focus on the tribes. (p. 138). They have the truly profound and moral view of wolves. As they state in their submissions, the approach is not to "manage" their brother wolf, "but instead provide stewardship or non-lethal coexistence." (Forest County Potawatomi, p. 39). The Lac Court Oreilles believe that wolves should "self-determine their numbers and distribution on the landscape". (p. 40). This is absolutely right.

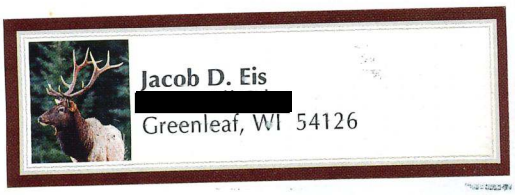
The wolf is sacred to the Menominee people. (p. 42). The Ojibwe speak not of "managing" wolves, and "not of dominion, but of reciprocity", and acknowledge "the inherent right of ma'iingan [wolves] to exist". (p. 43).

The Tribes have it right.

Respectfully submitted,

John F. Ebbott

To Whom IT my concern



I find 2 flaws In your wolf mangment plan.

1. allowing a Sovereign nation CanTrol over privite property

2. no population goal and no number for capacity

I ask That These Issues be adressed

Thank you

I AGREE 350 WOLVES IS A NUMBER THE STATE COULD LIVE WITH, OR GIVE THE WOLF THE SAME STATUS AS THE COYOTES. RIGHT NOW THE DNR IS UNDER THE CONTROL OF THE ANTI-HUNTING GROUPS. RANDY JOHNSON NEEDS TO WORK WITH THE HUNTERS AND TRAPPERS.

Regarding: Wolf Management Plan Comments

Dear Mr. Johnson:

Thank you for the opportunity to comment on draft Wolf Management Plan. I hope that you will give due consideration to those of us who live and share our land with wolves.

1) The plan must have a specific, numeric, population goal to manage for. While this number will be difficult to negotiate to start with, it is a critical starting point and a way to measure the success or failure of various management steps, when and how much to harvest, ect. This number can be amended in the future. But there must be a number to start with.
2) There should not be a buffer area around reservations. This is not biologically needed and it is simply contrary to the rights of adjacent landowners. Would you or I like to have a buffer from various activities around our home or the land we own? Sure we would, but that isn't fair to our neighbors.
3) Clear and effective way to handle wolves causing conflict. So far I have not had any livestock losses due to wolves, though they are sometimes very close in vicinity. But I would be much more accepting of wolves and a higher wolf population **IF** I was confident that "problem wolves" could be dealt with in a quick and effective manner. Right now I am not confident this is the case.

I share many of the concerns that WWF has with the plan and when you work with them, you will be addressing the concerns of many people like me, that are usually silent, but concerned and more directly affected by wolves than Wisconsin's urban population.

Thank you for your consideration!

Sincerely,

Scott Fischer

Dear Randy Johnson:

I have been a Wisconsin resident and involved in hunting and conservation for most of my 72 years of life. I manage a 92-acre property for Concordia University Wisconsin here in Shawano. I am a Snapshot Wisconsin member and know the majority of our local DNR staff personally, and have purchased the conservation license yearly for many years.

I'm writing to comment of the proposed Wolf Management Plan. I did take the survey when it was first offered. I found it perplexing I could not use my Wisconsin Switchboard log in to access a place for comment as was stated through the Wisconsin Outdoor News article in the Dec. 30.2022 issue. I live near the Menominee Indian Reservation and have native friends, so I understand their feelings for the wolf. I appreciate the complexity in balancing policy with ceded territory.

My major issue with the proposed plan is the lack of population goals, and the lack of weighted input from the people who live with the effects of wolf densities. This proposal appears to favor the interests of people groups who contribute the least to fund the WI DNR and WI wildlife populations, and results in a loss to those who do so by taxes and license fees. I am concerned this approach will mirror Minnesota's policy to wolf numbers and their effect. I have hunted in Minnesota's St. Louis County for 15 years as part of a hunting camp with a 50-year history. I have watched the deer hunting descend to its present deer population of .21 deer per square mile. I have seen the hunters decline and the loss in people renting hotel space in Hoyt Lakes, Mn, not to mention the resident people who really rely on the yearly venison. The camps and trucks along the road decline every year. This year our camp of 5 hunters (who are good, all-day-in-the-stand hunters) saw a total of 2 does, 3 fawns and 4 wolves. This is the third year in the last four without a buck on the pole, so we can't recruit new members. Our camp will cease to exist in the future and that revenue will be lost to to the local area and the state. I have asked the Hoyt Lakes hotels what they estimate their income from wolf enthusiasts is and their response is "Negligible". They simply don't come up to hear the wolves or or use the area. That is a wasted effort for tourism. We don't want this to be Wisconsin's future.

Sig Olsen, the man responsible for the 'Boundary Waters' said in his autobiography that he thought 300 wolves was what it took to balance that vast tract. Adrian Weydeven(who pioneered our re-introduction of the wolf) also has advocated for clear population goals. As Adrian has warned, without a population goal limit, people will just kill wolves; they will self-regulate.

I think you must consider the present level of anger in our society when you propose to impose an unwanted situation. I have seen the impact of high wolf numbers and deep snow change a wildlife population to where I don't know if it can ever come back (it is a silent northern Minnesota woods). Unless the people from Madison and Milwaukee are willing to start to subsidize the WI DNR (and would agree to have 200 wolves released in *their* counties) something has to change in our management strategy.

I agree the reporting system changes for a wolf hunt should change, and high-density areas should have more specific and higher harvest numbers(perhaps use the deer area units to target). I do think it is beyond foolish to give part of the harvest goal to the reservations, as they consistently will not take any wolves! Be straight forward and honest, and raise the hunt/trap numbers to reflect the reservation allotment. We need to get the wolf numbers down to a sustainable level for the future for wildlife and people.

Sincerely,

Orren Fredrick

Wolf Management Plan Comments

101 South Webster Street

PO Box 7921

Madison, WI 53707-7921

To the Department of Natural Resources

I read your Wolf Management Plan, all 167 tedious pages. It is very thorough and complete, except for the "management" part.

Let me as direct as possible – there are too many wolves in this state. They are decimating the deer herd in areas that they have populated and have significantly reduced the hunting opportunities for hunters that own or lease hunting land in those areas. Even worse, the DNR appears to be content with the present situation and has no plans to reduce the wolf count. Instead it appeases many groups who have little or no direct connection to the wolf population to the detriment of the 500,000 deer hunters who buy 500,000 licenses and provide $2 billion of economic benefit to the state every year.

Hunters had to drag the DNR to the courtroom to make it have a 2021 wolf season that it was required by state law to do. To add further insult to deer hunters, its quota for that hunt at best could only stabilize the wolf count and at worse allow it to grow even higher. No wolf season was held in 2022 and, more than likely, there will be no wolf season in 2023. Meanwhile the wolf count will only increase. Nothing in your feel good Plan discusses what the DNR intends to do about a potential future wolf count of 1,500 when there finally is a wolf season.

There was a time before the wolves showed up when my hunting companions and I would kill several does between bow and gun season to keep the deer herd in check. Those were great times. We filled our freezers and used quality deer management. Now we do not kill any does in a desperate attempt to maintain a very diminished number of deer. So the wolves now fill their bellies and our freezers are as empty as your Plan.

The emotional satisfaction that I get from my hunting land is far less now than before there were wolves simply because there are fewer deer and fewer opportunities for hunting. A woods void of deer does not make for a great hunting experience. Where is my compensation from the DNR for my diminished enjoyment of my hunting land? At least farmers are partially compensated for their loss. We all know that wolves will be with us forever, but their number has to be reduced to a number that allows a healthy deer population and provides meaningful opportunities for the people that hunt them. Your plan is almost silent on the subject and needs to be changed. You have abandoned your original goal of 350 wolves, but 1,000 plus wolves is too many. Reduce the count to a number that is reasonable for all of the parties, including deer hunters. The DNR cannot have wolf seasons that do no more than sustain an elevated and unacceptable number of wolves.

Any future wolf season also needs to be changed so that trappers and callers have a chance to hunt and trap. Since 86% of the 213 wolves killed during the last season were taken by dog hunters within 48

hours, it is obvious that hunting with dogs is too efficient to allow for a meaningful season for others. I suggest a two week period for trappers and callers and then let dog hunters have their turn..

Wolf management Plan Comments

101 S. Webster St.

P.O. Box 7921

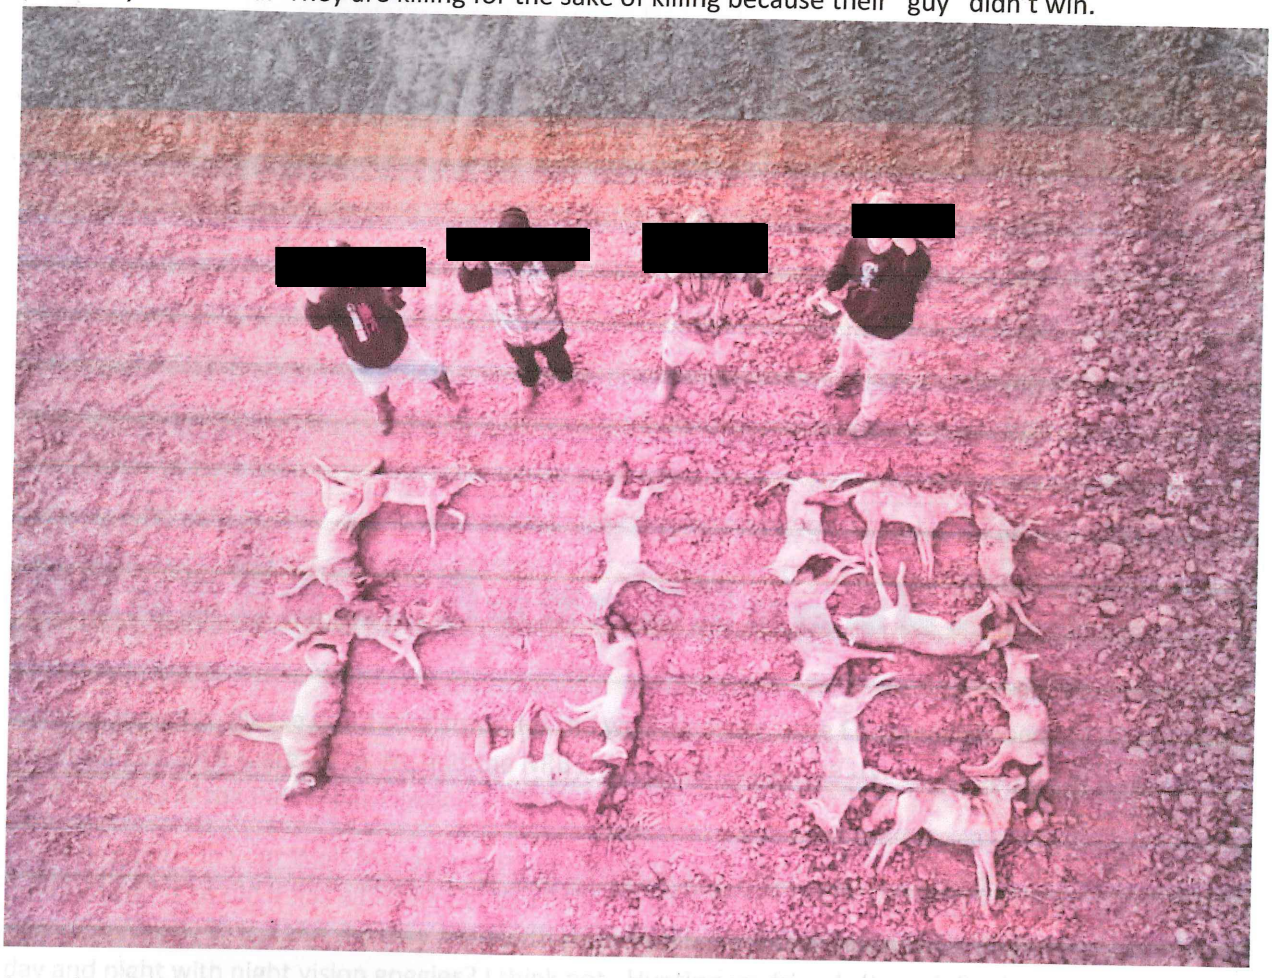
Madison WI 53707-7921

Wolf Management Plan Draft Committee,

While this is an improvement over the previous very old plan, it uses literature from some 50 years ago to substantiate certain points. There are much more recent studies that have been done using tried and true real Science, and not just opinion or anecdotal evidence. Where the sampling is very well documented and accurate. Your study having authors from "the office of Applied Science: without PHD's or Biologist behind their name doesn't sound too scientific to me. Disparaging "Vegetative Regeneration and Biodiversity" which was as recent as 2016 does not bode well either. Where exactly is the proof that it is biased or inappropriate sampling? I will be sending a list of reference material that is recent, and I would hope that at least some on this new management plan will read at least some of the listed materials. They are all certainly more current.

I am also very pleased that there is no 350 goal. When our neighboring state somehow manages 3,000 wolves with zero Fiasco's like ours in February just after the delisting 2021. But you do at least acknowledge the ecological role of wolves. HERE where I live, we essentially have 3 known packs that surround where I am, and amazingly we have no CWD here. Hmmm I wonder why? Why... SOMETHING seems to be selectively removing affected animals who are obviously slower, walking in circles they are quickly removed from the landscape. The DNR did a huge massive kill off years ago, and the result was the exact same percentage of CWD affected deer before and AFTER that massive kill off.

I am also including a survey of Wisconsin residents who checked off ALL of the outdoor activities that they participated in. Hunting in general was 27%. When the survey showed over 60% are non-consumptive users in multiple categories. The climate of shoot everything because it moves is changing.

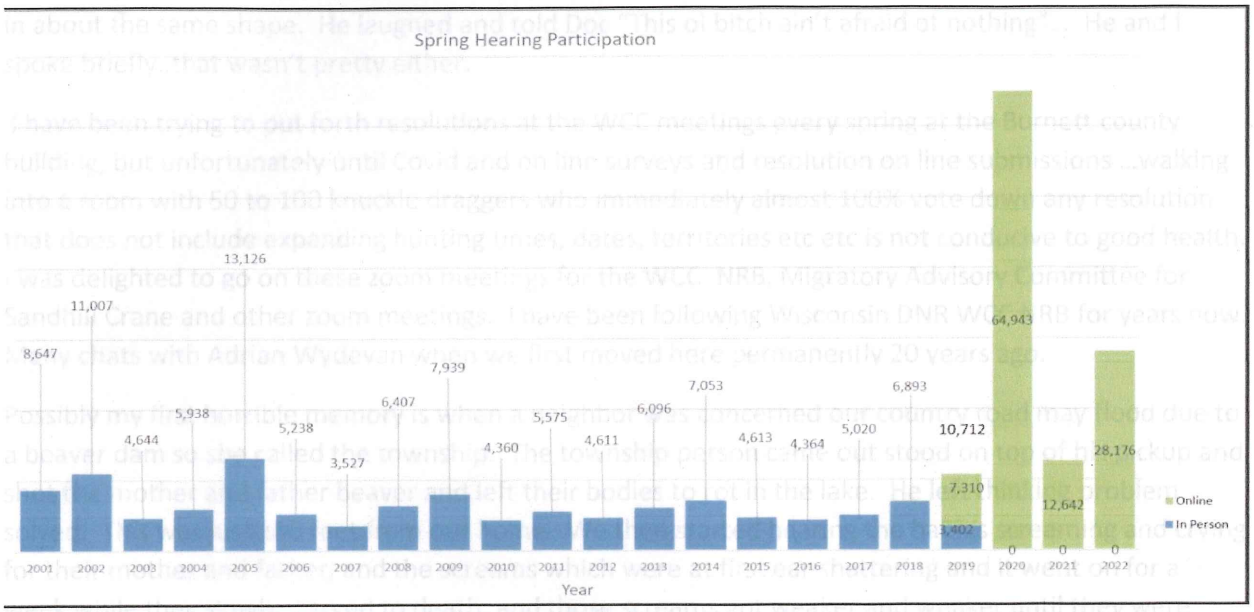


Activity group	% of WI residents that participated at least once in last 12 months
Hiking	68%
Hiking/walking/running on trails	
Nature observation	66%
Bird/wildlife watching	
Nature photography	
Gathering berries, mushrooms, etc.	
Boating-related	61%
Motor boating	
Canoeing/kayaking	
Personal water craft (jet-ski)	
Sailing	
Stand-up paddle boarding	
Waterskiing	
Fishing	49%
Lake fishing	
Stream/river fishing	
Ice fishing	
Camping	41%
Tent camping	
RV/pop-up camping	
Dog-related activities	38%
Walking/running dog on trails	
Visiting a dog park	
Bicycling	35%
Bicycling on rail-trails or other developed trails	
Mountain biking	
Fat tire biking/snow biking	
Hunting	27%
Big game hunting	
Turkey hunting	
Small game hunting	
Migratory bird hunting	
Motorized trail-based activities	25%
ATVs/UTVs on trails-routes	
Snowmobiling	
4-WD vehicles on trails-routes	
Motorcycles on trails-routes	

Your authors include among them various wildlife advocates, (but I have to wonder having watched multiple WCC, NRB meetings on zoom due thankfully to COVID if they were listened to and given a chance to speak). I watched the WCC and NRB panel struggle to stay awake while in one interaction a female ACTUAL Biologists who were called "HON" were asked if they felt an "EMOTIONAL attachment or connection to wolves?" How demeaning… (on video during zoom NRB meeting) But kudo's for having at least SOME Wildlife Advocate Associations, Alliances, Federations on the panel for this new Wolf Management Plan.

Non-Lethal measures should be used, insisted upon, if any compensation for lost livestock due to predation by substantiated wolf kill is requested. No mention of Non-Lethal measures although they have been proven to be effective elsewhere.

I raise French Bulldogs, I have a 6' high cyclone fence. I live in the middle of 3 known packs of wolves, and in 20 years full time and an additional 15 part time years here have never had a problem



with wolves. I have however had a problem with packs of hounds on my own property and my neighbors' property (1,000 plus acres that I watch for Mark O. Johnson) Blocking the roads, sitting in their pickup trucks watching a screen, and not moving until they hear that bear/wolf/coyote is surrounded or treed. I can step outside and hear packs of hounds baying anytime in the day or night hunting or tracking "something" almost 365 days a year, and if you ask me they should never be allowed to hunt wolves ever under any circumstances. That is nothing but a dog fight in the woods. This behavior encourages a lack of respect for life, a blood lust, a barbaric sadistic ritual that encourages these individuals to turn their barbarism to humans in some cases. Every serial killer has a history of dissecting or killing small animals before graduating to humans. These hounders are the lowest among the hunting population. They get no respect from traditional hunters who fill their freezers with venison to feed their families. There is no Wolf stew recipe. This is WANTON WASTE...politically motivated. I have pictures of F J B written in dead Coyote bodies (F@#$ Joe Biden) so don't tell me that is not politically motivated. They are killing for the sake of killing because their "guy" didn't win.

But I digress. Talking about politicization of killing wolves. The chairman (Kazmierski) of the NRB after the February Fiasco of an extra 99 wolves killed in under 3 days was suggesting a quota of 500 (video tape of NRB meeting) for the SECOND hunt in the same year (against act 169), but calmer heads prevailed and they only sent a suggestion of 350 to the DNR who rightfully so declined that number and set the quota to 130 giving the traditional percentage of that number to the tribes. THANKFULLY that second hunt didn't take place but this is just further proof that WE NON-CONSUMPTIVE USERS don't

have a voice and all of this WANTON WASTE KILLING is politically motivated. After watching multiple NRB, WCC zoom meetings since the advent of Covid I am getting a much clearer picture of WISCONSIN, and their NON CONSERVATION policies. Just this last week the WCC having ACTUAL input from Wisconsin Residents has VOTED OUT the 3/2 rule which was 3 counties 2 years in a row and the resolution proposed by a Wisconsin Resident will move to the Spring Survey. Now it goes to their committee where it falls asleep with the members of the WCC. The WCC also talked during the past 3 meetings about eliminating the ZOOM and on line surveys because of too much participation. One panel member said "YEAH can you imagine if we have the Spring Survey and 3,000 people show up in Dane County??? NOT political???? I think not.

Here is the participation in the WCC zooms with the advent of COVID. People CARE! We pay exorbitant real estate taxes, shop locally, and deserve to be heard. This bar graph was sent to me by Kari Zimmerman upon my request.

Another thought. Please don't take credit for the wolf recovery....the Endangered Species List gets the credit for that...if it were up to WI, and the NRB they would already be trying to recover again, or have gone the way of the Passenger Pigeon.

Another point – In your Wolf Management plan Some of your so called "Scientifically derived information" is so old it has whiskers i.e. Van Ballenberghe 1975 talks about "After a wolf hunt the litter size increases by 31%....but did they hunt with snowmobiles, packs of hounds, loaded long guns hunting day and night with night vision goggles? I think not. Hunting my friends 'Just ain't what it used to be"

Similarly...Let's talk about the "LANDSCAPE OF FEAR" for a moment. Your Wolf Management Draft states the following: "Prey in the presence of a predator are more vigilant it says, they use the landscape differently, there is an increase in prey stress level, so they eat high quality forage and they have a reduced body condition which leads to prey decrease in reproductive outputs"...I'm sorry but this is 23 year old B.S. I am sure they have not considered the effects of PACKS OF HOUNDS

HUNTING/TRAINING/TRACKING ALMOST DAY AND NIGHT 365 DAYS A YEAR RUNNING THROUGH THE WOODS CHASING/TRAINING/HUNTING OF BEAR/WOLVES/COYOTE/RACOONS/FOX/BOBCAT ETC., ETC., but THAT doesn't hurt ALL the wildlife, and all those herbivore prey? Please...

OK, I think you know where I am coming from. But maybe not...We are meat eaters, we fish, we have friends that fill their freezers with venison every year to feed their families, and sometimes they share. I can't sleep with my windows open on cool summer nights because of the incessant gun shots and baying hounds, and pickup trucks racing up and down my country road. I raise fat little French bulldogs I call "wolf hors d'oeuvres" yet I have never had a problem with wolves, just packs of hounds, packs of hunters in pickups, blocking the roads, and the sound of horrific dog fights in the woods when a pack of hounds encounters a pack of wolves in the thousand or so acres surrounding my home. My Veterinarian Dr. Tom in Webster has stitched up countless Hounds. One day I was taking my bitch in for progesterone testing, and a hounder walked in with his bitch who's entrails were hanging down by his ankles, and he had some clutched in his bloody hands. I had to wait because she needed immediate attention, and he handed her alive over to Dr. Tom and told Doc that he had another one in the Pickup in about the same shape. He laughed and told Doc "This ol bitch ain't afraid of nothing"... He and I spoke briefly..that wasn't pretty either.

I have been trying to put forth resolutions at the WCC meetings every spring at the Burnett county building, but unfortunately until Covid and on line surveys and resolution on line submissions ...walking into a room with 50 to 100 knuckle draggers who immediately almost 100% vote down any resolution that does not include expanding hunting times, dates, territories etc etc is not conducive to good health. I was delighted to go on these zoom meetings for the WCC, NRB, Migratory Advisory Committee for Sandhill Crane and other zoom meetings. I have been following Wisconsin DNR WCC NRB for years now. Many chats with Adrian Wydevan when we first moved here permanently 20 years ago.

Possibly my first horrible memory is when a neighbor was concerned our country road may flood due to a beaver dam so she called the township. The township person came out stood on top of his pickup and shot the mother and father beaver and left their bodies to rot in the lake. He left thinking problem solved. This was just 100 feet from our home. We then started hearing the babies screaming and crying for their mother and father, and the screams which were at first ear shattering and it went on for a week while they slowly starved to death, and those screams got weaker and weaker until they were silent. We had no way to get to them, we called the DNR to no avail. I moved from the Concrete City of Chicago to be with wildlife, to photograph it, to enjoy it, and THIS barbarism is what I found. Shame on Wisconsin for allowing these barbaric wolf hunts and Coyote killing contests both of which are WANTON WASTE of our natural resources with no thought to us non-consumptive users of the outdoors, sustainability of our wildlife, nor the consequences of packs of hounds disrupting wolf pack hierarchy. Our voices have not been being heard. THAT NEEDS TO STOP.

More examples of Wanton Waste from just ONE BAR called Brothel Tavern where they have Squirrel killing contests, Coyote Killing contests to generate revenue several times a year.

Suggested resources for more current information for Proper Science based Wolf Management Plan follows.

Sincerely,
Merri Ann Gonzalez RN

BROTHEL
SMOKE A PACK A DAY!
COYOTE CRUMP
TAVERN

JAN. 6TH-8TH

4TH ANNUAL COYOTE CRUMP

2 Person Teams $50 entry

PAYOUTS FOR LARGEST MALE, FEMALE AND MOST COYOTES

All entrants get a chance to win a BOG Deathgrip Tripod
All entrants receive a Brothel Coyote Crump window cling

JAN. 21ST

4TH ANNUAL SQUIRRELMAGEDDON

2 Person Teams $40 entry

MUST SIGN UP BY JANUARY 20TH
REGISTRATION 3PM SHARP @ THE BROTHEL
LIMIT 10 SQUIRRELS PER TEAM

CATEGORIES PAID:
GRAND CHAMPIONS • TOP 10% OF ENTRANTS AFTER CHAMPS • HEAVIEST OF EACH SPECIES
LIGHTEST OF EACH SPECIES • TOTAL TEAM WEIGHT • OLDEST & YOUNGEST HUNTERS

*Species score: Pine, Fox, Black, Grey
**Point values drawn after registration
All entrants receive a Brothel Squirrelmageddon Cinch Bag
All entrants receive a chance on a Rossi 22WMR Semi Auto
Each squirrel registered = 1 chance on a special gun raffle
- Ruger 10/22 With Scope
Every 2 squirrels registered = Drink Chip

About | Discussion

To whom it may concern

I have read the proposed new wolf Management plan and have concerns.
The new plan would have no cap on the population of wolf. There should be a cap. Many county boards voted to have a cap set at 350.
I also have a problem with allowing sovereign nations control over private property rights Please concider these concerns before moving formard.

Thank you
Michael Hunter
[redacted]

General statement of Draft Wolf Management Plan, prepared by Laurie Groskopf

Wolf Management should be pretty simple. If you believe that wolves should take up habitation everywhere within their pre-settlement territory, few controls will be applied to their location. This characterizes the draft WI Wolf Management Plan as presented. If you believe, as the experts recommend, that wolves are safer and able to survive in a more natural state, by avoiding human interactions and exposure to agriculture, along with adequate prey, controls need to be applied.

Thanks for extending the public comment period. I intend to continue to promote public input as not having a real advisory committee since October, 2014 has resulted in many blunders and intentional misguided management of wolves by DNR. We MUST HAVE A FUNCTIONAL ADVISORY COMMITTEE AT ALL TIMES, like we do for other species and like we always did (sometimes 2) before October, 2014.

Public meetings should have been held. At the virtual zoom Feb. 7, 127 people signed up and about 54 spoke. At the Wildlife Federation/WI Assoc. of Sporting Dogs listening/sharing session in Solon Springs, Douglas Co. Feb. 18, 60 people attended in person, including a few by zoom. The audience recommended more listening sessions in person in wolf country. Denying citizens a voice, particularly a smaller minority such as rural citizens directly interacting with wolves, does not promote good wolf management. Those who are directly living with wolves have a much greater need to approve and accept a wolf management plan, and promote wolf safety and security. In the absence of agreement with the wolf plan, those same people are motivated to not support the plan and develop their own management strategies.

Clearly Local and County government were not included in the planning process. Many elected local bodies of government have formal resolutions regarding wolf management. These governmental bodies, as well as the legislature, has a stake in wolf management.

The latest 2 wolf management plan committees were heavily weighted towards wolf protectionists and wolf expansionists. On the plan committee, 8 of 29 were tribal representatives. 6 of 29 were wolf protectionist organizations, 4 of 29 were partners or sub-contractors of DNR who naturally would not care to disagree with any plan, 4 of 29 were agricultural groups, 6 of 29 were hunting/trapping organizations. One was undetermined as to their stance, but tended towards protectionism. This count is 10 for wolf controls, 19 for expansion. This is a 1/3 to 2/3 split.

The wolves themselves would tell you they don't care if there are 1200 of them in WI or just enough for peace and quiet, a place away from humans to survive, and enough mates to keep packs going. Managing for the assumed majority opinion may be doing the wolves no favors. Conflicts, both documented and the many more incidents that are not documented, increase intolerance. We know from research and the records that increased exposure to human presence and agriculture increases conflicts. This further degrades wolf/human relationships. It also causes other impacts, such as loss of grazing opportunities, reduced livestock health and production, increased expenses, etc. Some people are going out with sidearms whenever outside. Families are reluctant to allow their children to play outside unattended. WI DNR totally ignores the risks associated with expansion of wolves into human and agricultural occupied areas with the draft plan. To justify this, a general survey with a response rate of 3158 (possibly 20% of this responding that they were not interested in completing the survey?) was used to assume more people wanted the program to expand than to implement controls. Again, this survey sample cannot possibly represent the relative minority of WI residents that are regularly interacting with wolves. A response rate of 3158 compared to an 18+ population of 3,994,919 is not

capable of capturing the most important human opinions – the people that can make life hard for wolves or respect the management plan and agree with its goals. Inevitably, the unmanaged expansion of wolves has led to low tolerance. DNR disregards this minority view with its methods. The lack of public hearings in wolf occupied areas clearly indicates that DNR does not care to consider the rural, wolf-exposed minority views.

The survey design is flawed, as is MN and MI surveys, and others patterned after this expansionist view of wolf management. Polling the general public on any topic primarily impactful towards a minority is dismissive and discriminatory. Repeating previous mistakes does not give our WI DNR survey more credibility. County-based units are too large and many highly influenced by urban people or those who live in dense recreational housing. Too small a sample return, use of zip codes for sample, and multiple other errors are features of the DNR Public Opinions Survey.

The occupancy model of tracking was supposed to save money and provide more reliable estimates. I have been a volunteer tracker for 10 seasons. Our tracking surveys over the years have provided insufficient data in at least 40% of tracking blocks to yield good information for estimates. Many blocks have been discontinued due to DNR lacking evidence of wolves within those blocks. But these same blocks are represented within wolf zones and expansion of wolf zones, for the reason that wolves have been noted in these areas. Total miles tracked for the entire tracking efforts gives little credibility to each blocks performance. Each block must be tracked adequately in order to have any reliable numbers for estimates. That would indicate a good quality tracking program. Other sources of presence of wolves need to be incorporated into the estimate (game cameras, public reports). As of now, any reports made will not be included in that winter's data, but delayed for a year to direct tracking effort in the next year. Only 18 collared wolves are on the landscape from DNR and only 6 of those collars are working. There used to be many more collared wolves with functional collars. Instead of being an improvement, the tracking program now is more expensive (about ¾ of miles by paid staff) and does not have a diverse base of information utilizing hunter reports and game camera detection from the 100,000+ citizens. It does not even use any public reports of wolves after the tracking season begins. This would never have happened with a functional advisory committee.

Wolf experts agree at any time 10 – 15% of wolves are lone or dispersing. This amount may vary during the year, but is relatively high during pre-mating season and as pups mature and adults may decide to leave. We have decades of tracking information that would be very easy to recover data on Wisconsin's loners and dispersers. While some of this is transitory, there are also documented cases of lone wolves that stay solitary over a longer period of time.

Current probable or confirmed public reports are not being used as part of the current winter's estimate DNR statisticians are not familiar with pack dynamics that could easily identify packs from various sources of data. There is too much unnecessary complexity to the occupancy model. If packs are averaging 65 square miles of territory, clusters of occupancy would define a pack territory easily.

Not enough GPS collars that are functioning are being used on the landscape. Previously, not enough variation in location for placement of GPS collars. Can't PR funds be used to improve this? We are not flying the older collars anymore, and are saving a ton of money?

The plan states its intentions to reduce conflicts, but provides no methods to do this beyond the historic non-lethal abatement that is effective temporarily for a particular location, but the impact diminishes as wolves become habituated, and the wolves just move down the road to another farm or another

hunting dog or pet. The plan does not compensate for actual losses caused by wolf conflicts. Market value is a far cry from the eventual value of an animal. Also, loss of time for addressing conflicts, materials such as mending fences, maintenance of abatement measures, loss of production value, and psychological impacts, which can be very intense and long-lasting, are not compensated. One can only call this program a payment program, not a reimbursement or compensation plan. Zone 4A was previously included in zone 6 – unsuitable habitat. Moving it to a secondary wolf zone, Zone 4, means less quota will be available in this area. This is not an improvement on a situation where clearly, this portion of Wood Co. as well as other portions included in Zone 5, are determined to be in a wolf zone where they do not belong. (See Theresa Simpson "Location Matters: an eighteen year spatial and temporal analysis of the recolonization of a disjunct population of gray wolves" master's thesis, 2019). MI has previously eliminated wolf packs in areas where hunting dog depredations were excess. Not done often.

Using the conflict list to measure success is very unscientific. These lists are variable due to conditions and the status of wolves. When listed, citizens are more reluctant to report conflicts, preferring not to draw attention to a solution they feel is in their hands. Only a population goal or range, as MN is promoting (2200 goal, range 1600 – 3000) might turn the tide of the tsunami of conflicts we are experiencing. As the DNR is not interested in measuring the tolerance of wolves in the small population directly impacted, there is no way to measure tolerance as it appears on the ground. We do have data that 89% of wolf mortalities in WI is human-caused. It is not difficult to measure wolf numbers and know their areas. Wyoming has successfully kept their wolf numbers under 350 (including Yellowstone) for over 14 years, and had small seasons during desilting years.

The DNR's myth that wolves live only in remote areas was caused by inexperienced staff at the beginning of the program. See page 18, Mech and Boitani "Wolves, Behavior, Ecology, and Conservation, 2003 for specific information on wolf expansion in MN. Wolves use roads. Experts would have known that wolves are adaptable and resourceful, wishing to survive over the alternative.

All conflicts need to establish a 4-mile radius warning areas around the event. The mapping feature on line is not informative enough to provide this information. WCC and Wildlife Federation have both passed resolutions supporting the 4 mile radius warning. Wolf pack territories are now estimated at 65 square miles average. A 4 mile radius is 50 square miles. The lack of a warning area is a lawsuit waiting to happen.

I find your discussion of the non-depredation impacts on livestock on page 75 and the Human health and safety risk perception to be totally inadequate, and in some measure, insensitive and discriminatory towards the rural population directly exposed to wolves. These encounters are often dismissed as "perceptions" based on fairy tales. Many of us can personally attest to the fact that harassments, conflicts, threats, and close encounters are not products of an overly active imagination, but are real and frequently traumatic events. In addition, it is insulting to see the comparison of the risk from bears, coyotes, and domestic dogs you place into the plan. There are many more bears, coyotes and millions of dogs. To compare those risks to wolves is demeaning. Bears destroy property like corn fields. You cannot compare a flattened corn patch to losing your 13 year old black lab to a wolf 50 yards from your front door. You cannot compare it to losing 30 years of breeding sheep in one night, and having your family come over to dispose of the mangled dead, and a few still living but doomed to be dispatched animals. You cannot compare these events with losing two cows in the process of delivering calves – each one week apart, a loss of 4 animals, within 200' of your house in a pasture – and never seeing your pet dog again during the first attack. How can DNR be so insensitive? Rural lives matter!

Removing virtually all harvest from tribal buffer zones erodes private property rights, and could set a precedent for other species management. Bears and other animals have clan significance and spiritual qualities, and could be claimed as managed by the tribes. DNR has decided to provide tribes this additional right through harvest quotas and by virtual exclusion of harvest zones. In the past tribal treaty rights of quotas were not granted to game animals if the tribe did not harvest at least 15% of the quota. This has changed, and could change for other species.

The proposed zones are not supported by any science. Neither the previous plan zones, nor the currently proposed zones follow the science. The only studies done in WI, and there are 4 – are David Mladenoff's. These studies reveal 5,850 square miles of primary wolf habitat (absent human presence, absent agriculture, enough game to eat). In 2008, a repeat of the study increased secondary habitat due to wolf expansion. This did not mean the environment became more suitable for wolf habitation. It just meant wolves had to expand somewhere, and being territorial, had no choice. The primary zones stayed essentially the same. Mladenoff cautions in this study that just because wolves are living more in secondary zones, does not mean decisions should be made to encourage them to continue this trend. The primary zones were largely large forested areas. Since the 1990's when these studies were done, large divestments of paper company lands has occurred in WI. Due to the change to hedge fund timber management, 1/3 of that private paper company land is now in private hands. As a result, these lands are fractured into smaller parcels, and many do not conform to the large forested previous status that provided primary wolf habitat. As Mech states in "Where can wolves live and how can we live with them" 2017, "Some zones for some periods can support total protection, whereas in others, wolf numbers will have to be reduced to various degrees or removed. They are prolific, disperse long distances, readily recolonize new areas where humans allow them, and are difficult to control when populations become established." We are now at the point where wolves have become highly established in areas of unsuitable habitat, and controls will be difficult or impossible from here forward.

Theoretical scientists have developed models that estimate biological carrying capacity for wolves at just over 1200 in WI. That level has been reached. These researchers are self-proclaimed experts that have not done real world wolf research. One glance at the conflict chart on-line tells us that there is an unacceptable level of wolf conflict. Wolves have surpassed their social carrying capacity (even Time Van Deelen said this in his presentation at the International Wolf Center World Symposium, 2018). No stated methods or techniques to reduce wolf populations were presented in the draft plan. We need a numeric target to reduce conflicts to close to zero, and reduce wolf numbers until this happens.

Dave Ruid, USDA wildlife services N. region Supervisor, has given a very good presentation on how implementing non-lethal abatements in Douglas Co. caused wolves to move from farm to farm causing new conflicts. Non-lethal abatement is usually only temporarily effective. Also, what may look like effectiveness may be the producer's natural instinct to protect their farm or property from more conflicts. It is important when claiming to support reductions in conflicts to deliver effective methods. The DNR needs to understand that policies aimed at increasing wolf presence in unsuitable habitat will naturally lead to higher level of conflicts and less human tolerance. MN currently defines wolf habitat as 28,561 square miles, approximately 1/3 of the state. Wisconsin proposes to have about the same number of square miles as appropriate wolf habitat, about 53% of the land area. Is there a reason WI has to have the second highest wolf population in the lower 48? See previous discussion on MN plan wolf goals and range. Wi has the highest human density by far in wolf occupied areas of any state in the lower 48.

There is no issue regarding long-term sustainability of wolves in WI. Besides having the second highest number late winter in the lower 48, we have excellent connectivity to MN, MI and Canada on both sides. We also know from GPS collar tracking that wolves are very capable of migrating long distances, for dispersals. In my neighborhood, a wolf was caught by a trapper and collared. It went to MN, and ended up taking up residence in Bayfield Co. In other states, wolves have been documented as travelling thousands of miles over many states and Canadian territories. Having a functional advisory committee would help explain all these misperceptions. We have not had a real advisory committee since October, 2014. Prior to that, even when wolves were on the ESL, we had at least one advisory committee and sometimes two. Lack of a balanced and functional committee has resulted in poor decisions and many errors of judgement. Every other species has an advisory committee, including the endangered marten.

Your harvest charts are a textbook definition of the self-fulfilling prophesy. We were told harvests would start to reduce the wolf population in 2012 – 2014. Using the Layne Adams study and Fuller chapter in Mech's book – both very old information that happened mostly in Canada and Alaska and was done long before any harvests in the lower 48, led people to believe you were relying on "science". The predictions of decrease in wolves proved false. After 3 harvests, WI only counted 69 less in the overwinter minimum wolf count after 2014. We now have 4 years of harvests that clearly demonstrate our quotas and permit rates will not reduce wolves by any substantial amount. This was the real agenda of the DNR. Again look at Wyoming, which has done an excellent analysis of appropriate wolf habitat. With 1 ½ times the area of WI, and 1/10 the population, they have maintained a stable population under 350 for many years, and held a small harvest when not under the ESA. Thirteen years of data from Idaho and Montana should also prove that the issue is controlling the numbers. These numbers include Yellowstone, where Wyoming agrees to maintain 100 wolves minimum.

Proper aging of wolf teeth by a scientific laboratory is recommended by three separate experts I contacted. Your chart of aging shows the bias that comes with having staff visually age wolves at harvest. This data created a firestorm of controversy when theoretical scientists used the data to predict the collapse of our wolf numbers. They were wrong. Your data was wrong. The quotas were insufficient and the aging needed to be done by scientific methods.

Data from our ineffective 4 seasons that did not reduce the wolf numbers, as well as data from 13 years of harvests in Western States, needs to be used to determine harvest quotas. There is much variability between the two studies used (only 1 - Adams in 2021) to determine quotas. As previously stated, the Fuller chapter in Mech's book published in 2003 assembled information on human caused mortality as it related to subsequent wolf numbers, and these studies were mostly done in Canada and Alaska. The Layne Adams study also assembled human-caused mortality data and wolf survival as part of his study in the Gates of the Arctic, published in 2008. Many of these studies came from Canada and Alaska, and none were done during the time of harvest in the lower 48. Using such research might have predicted DNR's preferred outcomes, but more current sources need to be used and developed to predict the impact of harvest. The success rates used were grabbed out of thin air. You can't accomplish a harvest in 2 ½ days of that magnitude in 2021, and a period of weeks in some of the zones of the previous 3 harvests, without something being wrong with the numbers, no matter what methods used and ideal weather. Everyone in wolf country knows this. Frankly, you won't like me saying this, but they think you are idiots.

The DNR has never taken any initiative to work with the federal US FWS to write a decent desilting order or work professionally towards delisting. People blame our relisting orders on liberal judges, but the reality is the delisting orders were not written properly. Relisting has always occurred not for biological

reasons, but for procedural errors. That message was clearly stated by US FWS representatives at the Ashland delisting hearing before 2012 delisting. It continues to be true today. It is time to be proactive and reach out to our US legislators and the US FWS to get us delisted if you really believe in state management. It is time to employ a seriously experienced legal team to defend our delisting orders. We need to address the minor issues with the last court rulings, both state and federal, and move on to managing wolves. Thirteen plus years to write a wolf management plan, and no revision of the emergency rules? This is a problem. The judge in California dismissed the plaintiff's claims that our management plan (the 1999/2007 plan) was not adequate to managing wolves. He felt our previous plan was fine. And so does the Department of Interior.

Attached are a number of documents that address my concerns regarding the Draft Wolf Management Plan. This plan is the most expansionist and protectionist plan that could have possibly be written. I am very distressed that the decades of advocacy from rural citizens directly exposed to wolves was almost totally disregarded in this plan.

My first wolf sightings were in Langlade Co. on Ormsby Rd. in the mid 1980's. Four wolves were in the road ahead, clearly very big and WOLVES. I don't think the DNR knew about them. My background in this topic advanced in 1995, when I moved to Harrison in Lincoln Co. and observed two resident wolves on several occasions. They were no trouble to us then, and it was different and a little exciting to see them. I don't think the DNR was aware of those wolves. Since that time I involved myself in learning about wolves. I became totally involved in June, 2009, and first spoke to the NRB about inaccurate and incomplete information being disseminated by DNR that summer.

I have attended a 2-credit course at the International Wolf Center, attended numerous conferences including the last 2 International Wolf Center World Symposiums in MN, three Midwest Wolf Stewards Conferences one of which I spoke at, numerous web-based trainings, the Northland College Conference by zoom, and spent thousands of hours studying wolf issues in the USA in other countries. I am in contact with experts all over the world on this topic. All this is done at my own initiative and I have never received any financial or other benefits from the organizations I belong to. In fact, it has been a very expensive personal quest from my own pocket. All this effort has resulted in absolutely no progress on DNR promoting delisting and working with the Dept. of Interior on writing a court-proof plan, or getting any meaningful measures of control over the ever-expanding wolf population.

Since 1995, I have been heavily involved in advocating for responsible wolf management in many capacities. I have spent well over 10,000 hours of effort since June, 2009, spent well in excess of $20,000 of my own funds to fund some of my projects and support efforts to effectively manage wolves, and frankly, no positive results have been realized by all this effort.

One of my first projects, based on David Mladenoff's work on wolf habitat modeling, the only scientific effort that has ever happened in WI, was to promote the wolf goal in the Wolf Plan (something DNR always have ignored since 1999) of 350. Because of Mladenoff's work, I felt 350 or less was a more reasonable goal, and I also promoted that concept. 350 or less was the social carrying capacity. 350 and 350 or less are not my preference for a wolf goal. I prefer to keep my opinion on the wolf goal to myself. However, approaching as close to zero conflicts as possible would be my goal. From 2009 - 2017, 36 county boards passed wolf control resolutions favoring 350 as the goal (7), 350 or less (26), or some lower number (3). These were sent to DNR staff and DATCP Secretary, legislators both national and state, and the governor's's office. They were ignored. This project involved hundreds of county board members, farmers, farm organizations, citizens and advocates.

When the latest of three attempts to revise the wolf management plan began, I re-contacted all counties involved and asked if they would wish to send in their previously approved wolf control, or would choose to pass another resolution. From that effort, again with the support of various county staff, county board members, and many citizens, 26 counties decided to again address this issue and either send in the previous resolution passed (9) or pass a new resolution (16). One new county passed a resolution that was not included in the original 36 (Chippewa). Sending old resolutions in were Outagamie, Barron, Grant, Marathon, Wood, Richland, Taylor, Washburn, Adams. Sending in new resolutions, in addition to Chippewa, Polk, Florence, Forest, Waushara, Jackson, Langlade, Lafayette, Marquette, Juneau, Price, Clark, Iron, Rusk, Douglas, Oneida, Lincoln. These resolutions were all sent in

for the public comment period, according to the county clerks I consulted. Counties that elected not to send in old or new resolutions, but had previously passed and sent wolf control resolutions between 2010 - 2017 were Portage, Shawano, Marinette, Ashland, Iowa, Sawyer, Burnett, Bayfield, Waupaca, and Oconto. Vilas defeated the resolution on a tie vote. I am still working with some of these counties to possibly take up the resolution.

Another project I worked on was creation of a new non-profit organization called WI Wolf Facts. This is a consortium of individuals that belong to farm and hunting/trapping organizations. It is mainly a communication group, with attempts to disseminate accurate information about wolves in WI. We ran Wolf Summit II, a conference that featured some national speakers as well as staff from DNR. We also helped run the recent wolf listening/sharing session in Douglas Co. In addition to general advocacy and information dissemination, WI Wolf Facts has recorded 7 videos featuring victims of wolf conflicts. Please take the time to watch these videos on wisconsinwolffacts.org and learn to understand the extremely long-lasting and traumatic nature of these conflicts on people's lives.

Another project I conducted in 2021 from Feb. - May was a large survey of rural attitudes towards wolves. Many of our rural partners - farmers, hunters, rural residents exposed to wolves, have advocated for the DNR to put a greater focus on those citizens that are impacted more heavily by wolves. Those same citizens are also able to impact wolves negatively, and they do so in large numbers. Unfortunately, citizen acton is the only true management in WI that has gone on over the past 30+ years. I have attached that survey and the map of my specifically chosen samples of rural towns that are not as corrupted by citizens who live in villages, towns or cities. Sampling within those units was every other voter name from town lists. This sample is just over 1/10 of the total state sample for your recent statewide survey. The response rate for this one mailing, stamped return envelope survey was much higher than one would expect, and compared with the DNR survey positively. All comments are contained at the end of the research. Please read the entire paper.

Another couple of projects I have worked on that are much smaller: an analysis of western human take and eventual wolf estimates in Idaho and Montana. This is attached, but not updated. However, nothing much has happened to change the results. While Idaho and Montana have continuously increased opportunities for harvest, and both states have a robust lethal depredation control program, as well as a partially state funded program to reimburse hunter and trapper expenses in areas identified by the state as needing more wolves removed, the problem continues to be a lack of control on those populations. While WI is not the Rocky Mountains, we need to hear the words of the experts that controlling these wolf numbers becomes much more of a challenge than any imagined issues regarding having a sustainable population. The days of worrying about a sustainable population in WI are completely gone, with high connectivity to MN, MI and Canada, and the second highest numbers in the lower 48.

David Mech says in his paper you include in the literature section "Where can wolves live and how can we live with them", Bioloigcal Conservtion, 210:310 - 317, "Some zones for some periods can support total protection, whereas, in others, wolf numbers will have to be reduced to various degrees or removed. They are Prolific, disperse long distances, readily recolonize new ares where humans allow them and are difficult to control when populations become established.". That piece of wisdom comes from a real wolf scientist who also has no ties but to tell the truth. At the International Wolf Center World Symposium, we heard that message over and over from real wolf researchers and managers. I hope Wisconsin will someday get the message, for the good of the wolves, and the good our our rural public and farmers.

Finally attached are just some of my many concerns about this wolf management plan point by point. I had to leave much out. Laurie Groskopf, Tomahawk, WI [redacted]

WOLVES: THE WISCONSIN RURAL PERSPECTIVE

SUMMARY

Wolves: The Wisconsin Rural Perspective, is the first survey measuring public opinions about wolves in exclusively rural areas of the state. These Towns are: Hansen, Wood Co., Russell, Lincoln Co., Maple, Douglas Co., and Alvin, Forest Co. A control Town, Richwood, Richland Co., was chosen to determine differences and similarities in opinions.

The survey is brief – two questions – with an additional item measuring respondents' exposure to wolves and knowledge of conflicts.

In the four Towns surveyed with wolf presence, 69.6% of respondents wanted less wolves in Wisconsin. In the control Town of Richwood, Richland Co., 46.7% of respondents chose "less wolves" in Wisconsin.

When asked their opinions about a potential wolf goal in Wisconsin, the most frequently selected option in the 4 wolf occupied towns was "350", "350 or less", or "less than 350" (55). The second most popular wolf goal in those 4 towns was "zero". Forty-five respondents chose this goal.

I began this project wondering about the differences I might discover in towns with varying amounts of time, different habitats, and intensity of conflict between wolves and humans. As it turned out, I am more impressed with the similarities and rather unified opinions about wolf management.

"Each time the proposed delisting has been blocked in court by protectionist groups arguing legal technicalities. This continued full protection for flourishing wolf populations creates a real problem, not only for farmers and ranchers, who are generally hostile to wolves, but also for the wolves themselves. Because when wolves proliferate where they conflict with people, they will be killed – legally or not ….We ….envisioned that once recovery had been met, the wolf would be delisted and where necessary, their numbers Controlled, like those of bears, deer, geese, and other wildlife." Wolf Island: Discovering the Secrets of a Mythic Animal L. David Mech, with Greg Breining. U. of MN Press, 2020.

BACKGROUND

Early wolf recovery in WI paid no attention to the social acceptability of wolves. Management decisions were focused on recovery of wolves, and it was believed by state managers that wolves would only live in large blocks of public land with little to no human presence. The concept of social acceptability as it relates to wolf numbers was not on the radar.

Studies of public attitudes towards wolves were small-scaled questionnaire-based studies (Nelson & Franson, 1988; Wilson, 1999, Schanning 2009). The results of these surveys showed support for wolf expansion. Some samples may have been biased. Schanning chose a representative sample, but had a very low return rate of less than 20% (source, unpublished preliminary draft DNR wolf management plan 4/10).

In 2001, Adrian Treves and others began a "Longitudinal Analysis of Attitudes Toward Wolves". Different samples were used for each stage, 2001, 2004, 2009, but some continuity in sampled respondents allowed for Treves to follow people's attitudes towards wolves over time. "Over time, 656 respondents increased agreement with statements reflecting fear of wolves, the belief that wolves compete with hunters for deer…and inclinations to poach a wolf." These studies took place between 2001 – 2009, when Wisconsin's minimum wolf count rose from 257 to 655. "Over time residents living in the range of Wisconsin's gray wolf became less tolerant of wolves." (Source, Conservation Biology, 2013) (Wisconsin Wolf Policy Survey: Changing Attitudes 2001 – 2009, Adrian Treves, Lisa Naughton, Tory Shelley)

A Wisconsin DNR study of public opinion released in 2014, in preparation for the second attempt to revise the 1999/2007 approved wolf plan, sampled 8750 addresses in Wisconsin with oversampling in wolf range. The study assumed that people with addresses in wolf areas would have had a greater exposure to wolves. "…human interactions should be more frequent in places where wolves occupy more space (with more wolves) and/or where there are more human settlements…To the extent that these assumptions are true, we expected to see some differences in the social carrying capacity of wolves across its Wisconsin range." (Public Attitudes Towards Wolves and Wolf Management in Wisconsin August, 2014, WI DNR)

For the sample areas identified as "wolf range" in Wisconsin's study, respondents self-identified as "rural" or "urban". The rural/urban split was one method used to analyze data. Opinions were split, with 40% of rural wolf country respondents rating their feelings towards wolves as unfavorable or very unfavorable, 22% neutral, and 38% favorable or very favorable. When it came to questions about how many wolves should reside in the state, 47% of rural wolf range residents wanted fewer or none, 24% wanted the same number, 16% wanted more or many more. The wolf minimum count was 809 while this survey was done.

Another method of wolf range data analysis consisted of large groupings of counties into one cluster. For example, one cluster was Bayfield, Ashland, Sawyer, Iron and Price Counties. Cluster data did not separate urban and rural, so may not reflect the most important population, rural residents, who interact more freely with wolves. In the above cluster of counties, 46% of respondents (rural and urban) indicated they wanted to see the wolf population decreased or eliminated in their county. 32% were in favor of the same number of wolves, and 11% wanted an increase in their county.

In another cluster – Burnett, Washburn, Rusk, and Taylor Counties – 50% of respondents wanted a decrease or elimination of wolves, while 31% wanted the same number (809 at the time) and 9% wanted an increase in wolf numbers.

This most recent study done by DNR staff noted the department and wolf advisory committee were particularly interested in "…the opinions of people living among wolves, especially in the rural areas, because those residents are most likely to encounter wolves and be impacted by them. People who are the most impacted by wolves are also the ones whose acceptance and cooperation are most needed to ensure continued success with management efforts." Sample selection and the method of reporting findings may not have captured the rural voice.

In late 2020, preparing for delisting, Minnesota completed research on public attitudes for their new wolf management plan. "Minnesotans' Attitudes Toward Wolves and Wolf Management" (Summary Report) U. of MN, MN DNR, MN Cooperative Fish and Wildlife Research Unit, Dept. of Fisheries, Wildlife and Conservation Biology, Schroeder, S.A, Landon, A.C., Cornicelli, L., McInenly, L. & Stark, D. 2020) targeted three groups in MN. These were: the general population 18+, sample 5250; Minnesota livestock farmers in counties within wolf range, sample 2500; and MN deer hunters 18+, sample 2000. These respondents were mailed surveys based on addresses with four follow up reminders.

Residents responded at 33%, deer hunters at 47%, and livestock farmers at 53%.

Livestock producers in wolf range were negative towards wolves at a rate of 62.2%. Their preference for a wolf population of "0", fewer or many fewer was 72.2%. Their preference for wolf range was none, much less, or less at a rate of 65.6%.

Deer hunters, a statewide sample, were negative about wolves at a rate of 51.5%. Their desire to see wolf numbers reduced to fewer, many fewer, or zero was 59.8% of respondents. They wanted wolf range of none, less, or much less at 48.3%.

The general MN population had a different outlook. Only 19.6% of residents had a negative view of wolves. Only 14% wanted a wolf population of zero, less, or many less. As for wolf range reductions, 11.1% wanted no range, less or much less.

This survey mirrors public opinion surveys in many areas of the world. Where people have little experience or exposure to wolves, attitudes are more positive. In cases where people have direct exposure to wolves and live near them, attitudes are much less positive.

In "On Wisconsin", a publication of the University of Wisconsin Alumni Association, Fall, 2009, Volume 110, Number 3, an article called "Wolves at the Door" by John Allen appeared. The article examined the opinions of UW faculty wondering how many wolves the state should have. "If you look at the habitat wolves currently occupy, it's not all good quality", according to David Mladenoff, Ph.D., the professor who first did population modeling of the landscapes in Wisconsin that could support wolf recovery. The article continues "And in the poorer-quality areas, the wolf population 'probably isn't sustainable'. The single most important habitat attribute which promotes successful wolf territory is lack of roads (and its companion, lack of people)." The article goes on to say both Mladenoff and Van Deelen, another UW professor

who has worked on wolf population modeling, believed in 2009 that the days of rapid multiplication may be coming to an end. In 2009, Van Deelen figured that 1300 wolves between MI and WI would be the maximum.

All these numbers and the vague concept of biological carrying capacity do the wolves no favors. The real importance of social carrying capacity is crucial to understanding wolf management. And keep in mind, no sensible person would advocate for wolves to be held at biological or social carrying capacity, because that implies we are willing to risk the wolves themselves and peoples' good-will towards wolves, by standing at the precipice.

METHODOLOGY

A study of true rural attitudes towards wolves was needed. This has never been done in Wisconsin.

Five rural Wisconsin Towns were chosen for this study. These Towns were not chosen randomly, but rather for their attributes. Attributes considered were the truly rural nature of each Town, length of time wolves had occupied the Town, and degree of conflicts experienced. Variation between towns was intentional to capture possible differences. The most important variable impacting the success of wolves is human population density. Previous research proves the more remote regions without human presence create optimal locations for wolves.

According to L. David Mech, in a keynote presentation at the October, 2018 International Wolf Center International Wolf Symposium 2018, in areas without human presence, wolves are the primary cause of wolf mortality. In human dominated landscapes, humans are the primary cause of most wolf deaths. The Towns chosen have varying degrees of human density, but all are without any significant settlements. The human density per square mile of territory is included in each Town description.

These five Towns chosen for this survey are: Town of Hansen, Wood Co., Town of Maple, Douglas Co., Town of Russell, Lincoln Co., Town of Richwood, Richland Co., and Town of Alvin, Forest Co. All Towns were chosen because they lacked cities or villages of any major size. This was needed to avoid areas where people have had little opportunity to interact with wolves.

The Town of Hansen in Wood. Co. (human population density 19.5/sq. mi.) has a mixed landscape of small farms and forested areas. Hanson straddles two wolf management zones, zone 5 which is considered by the department to be optimal wolf habitat, and zone 6, which is unsuitable wolf habitat. Some large public land is nearby, but Hansen is mostly private owners of small, sometimes agricultural, parcels. Wolves have occupied this area for about 10 years and have been a major source of conflicts recently, mainly with livestock, but also pets.

The Town of Maple in Douglas Co. (20.2/sq. mi. human density) has the longest history with wolves, well over 25 years. The landscape is mixed farming and rural residences, and the Brule River State Forest. Chronic problems and conflicts with wolves have been the experience of

this Town. Maple is located in Wolf Harvest Zone #1, considered primary wolf habitat by the WI DNR.

The Town of Russell in Lincoln Co. (18.7/sq. mi. human density) is a mixed landscape of forested areas and farms. Most of Russell is smaller private lands, with some agriculture present and a few public access areas of county forest and state fishing areas. Wolves have occupied this area for over 20 years, but have increased their presence for the past 10 years. Very few documented conflict incidents have occurred. Russell is located in Wolf Harvest Zone #4, considered to be sub-optimal or marginal wolf range.

The Town of Richwood in Richland Co. (14.5/sq. mi. human density) is located in the SW portion of the state in the driftless area. While very few wolves have been present in this area, and few problems have been verified, a control Town was needed to represent an area where wolves probably could live, but have not established permanent residence as of yet (as determined by DNR wolf tracking methods). Most of Richwood is private ownership. Richwood is located entirely in wolf harvest zone 6, which is considered unsuitable wolf habitat. But some advocate for allowing the establishment of wolves in areas such as this with a very low human density.

The Town of Alvin in Forest Co. (1.3/sq. mi. human density) was originally not part of the sample. But I had left over materials and wanted another wolf harvest zone represented. Alvin is quite different than the other sample towns because it is almost entirely lacking agriculture, and contains mostly USFS National Forest lands. Being located in Wolf Harvest Zone #2, it represents what the DNR classifies as optimal wolf habitat.

The survey sample was obtained from voter registration lists provided by county or town clerks. Using voter lists avoided return as undeliverable surveys common in address-based mailed surveys. Undeliverables were very low.

Sampling within each town was completely random, with every-other name selected and mailed the survey (see appendix to view the survey). The recipient also received a self-addressed, stamped envelope to return the survey. The mailing was the only contact with each respondent, except for a few that called to get more information and one who sent the survey back from the control Town stating that it was inappropriate as no wolves live there. I sent a personal communication back, since the person included their name and address explaining the concept of having a control town.

The survey was designed to be very simple, short, and not a burden for the recipient. This was primarily because many respondents will throw away a long survey. Also, context laden terms and questions used in previous surveys probably caused certain types of respondents to become frustrated or interpret the questions as invasive or leading the respondent. For this reason, the survey contained some brief, factual information followed by simple choices for the respondent to circle or write numbers. A “no opinion” option was also included. The respondent was given the opportunity to write notes, which are included as an appendix.

The total sample is approximately 9% of the recent survey sample for the entire state of MN. The sample used is 10% of the last mailed WI public opinion survey in 2013.

RESULTS - Response rates

The sample:

Town of Hansen:	247 minus 1 undeliverable =	246
Town of Russell:	208 minus 7 undeliverable =	201
Town of Maple:	241 minus 4 undeliverable =	237
Town of Richwood:	159 zero undeliverable =	159
Town of Alvin:	65 minus 3 undeliverable =	62
TOTAL SAMPLE		905

The sample consisted of every other name on the registered voter list obtained from the county clerk or the town clerk. The response rates for the five towns were quite good, considering this was a one-time contact from an unknown source. The five towns responded as follows:

Town of Hansen, Wood Co.: total sample 247 minus one undeliverable = 246; response from 119 = 48.4% responded.

Town of Russell, Lincoln Co.: total sample 208 minus 7 undeliverable = 201; response from 79 = 39.3% responded.

Town of Maple, Douglas Co.: total sample 241 minus 4 undeliverable = 237; response from 99 = 41.8% responded.

Town of Richwood, Richland Co.: total sample 159; response from 60 = 37.7% responded.

Town of Alvin, Forest Co.; total sample 65 minus 3 undeliverable = 62; response from 22 = 35.5% responded.

RESULTS – Less, Same, More, No Opinion

The survey questions asked whether the respondent wanted less wolves in Wisconsin, the same number of wolves in Wisconsin, more wolves, or had no opinion. (see full survey of 1 page)

Town of Hansen: Less Wolves 76.4%; Same Wolves 10.9%; More Wolves 2.5%; No Opinion 6.7%. There were also 4 surveys where results were contradictory. These included: 1) the selection of “same” but a quota suggested at 400, which would be less than current. 2) two surveys where the respondent selected “more wolves” but indicated a preferred goal of “0”, and 3) one survey selected “more” wolves but indicated a goal of 200. Inconclusive results totaled 3.4% of the total.

Town of Russell: Less Wolves 63.3%; Same Wolves 15.2%; More Wolves 5.1%: No Opinion 11.4%. Inconclusive 5.1%. For these inconclusive surveys, two surveys selected "More Wolves" but wrote a recommended goal of "0", one survey selected "More Wolves", but recommended a goal of 350, and one survey selected "More Wolves", but recommended a goal of 20.

Town of Maple: Less Wolves 65.7%; Same Wolves 11.1%; More Wolves 7.0%; No Opinion 12.2%, inconclusive 4.0%. Three inconclusive surveys selected "More Wolves" but recommended goals of 300 – 500, 100, or 350+. The fourth circled "no opinion" but wrote statements indicating fear and worries about conflicts.

Town of Richwood: Less Wolves 46.7%; Same Wolves 13.3%; More Wolves 10.0%; No Opinion 25.0%; inconclusive 5.0%. One survey questioned why Richwood was in the sample. I returned a response to this individual since he gave me his contact information, explaining that Richwood was the "control" Town because it was by some people's judgement suitable wolf habitat, but had experienced little presence of wolves. Another inconclusive circled both "less" and "same". A third selected "more wolves" but wrote a management goal of 500.

Town of Alvin: Less Wolves: 72.7%; Same Wolves 9.1%; More Wolves 13.6%; No Opinion 4.5%. All surveys were valid.

TOWN	LESS	SAME	MORE	NO OPINION	?
HANSEN	76.4%	10.9%	2.5%	6.7%	3.4%
RUSSELL	63.3%	15.2%	5.1%	11.4%	5.1%
MAPLE	65.7%	11.1%	7.0%	12.2%	4.0%
RICHWOOD	46.7%	13.3%	10.0%	25.0%	5.0%
ALVIN	72.7%	9.1%	13.6%	4.5%	0

RESULTS - PREFERENCE FOR STATEWIDE WOLF GOAL

Respondents were able to note their ideas about the state wolf goal. The results are as follows:

Hansen - Less wolves (91)
Goal of zero – 21
Goal of 350 – 17
No opinion – 14
300 – 5
400 – 4
Less than or equal to 350 – 4
200 – 4
100 – 3
500 - 3
Less than now - 2
275, 125 -150, 200 or less, 250, 50 – 150, less than 100, 0 – 500, 50, 150, 0 – 100, 0 – 200, 20, 450 – 650, 600 – Each received one vote (total 14).

Hansen same # wolves (13)
No goal – 9
1000 – 3
500 – 1000 – 1

Hansen more wolves (3)
None had any opinion on a goal

Hansen no opinion (8)
None had any opinion on a goal

Russell – Less Wolves (50)
Goal of Zero – 12
Goal of 350 – 11
No opinion – 11
Less – 2
500 – 2
100 – 2
0 – 350, 600, one, minimum, 350 – 500, 200, 250, 550, 850, 999 – each received one vote (10)

Russell – same wolves (12)
No opinion - 6
1200 - 2
1000 – 2
1034 – 1
400 – 1

Russell – more wolves (4)
No opinion – 3
2000+ - 1

Russell – no opinion (9)
No opinion – 8
350 – 1

Maple – Less Wolves (65)
350 – 16
Zero – 8
200 – 4
500 – 3
100 – 2
300 – 500 – 2
300 - 2

<350, 250 – 350, 500 – 700, 400, 700, <100, 1000, 450, 150, 800, small - all received one vote (11)
No opinion – 17 (chose “less” or no entry)

Maple – same wolves (12)
1200 – 2
800 – 1000, 1000, 1195 – 1 each
No opinion – 6

Maple more wolves (7)
1500 – 2
1200+ - 2
1400 – 1600 - 1
No opinion – 2

Maple no opinion (12)

Richwood – Less Wolves (28)
Zero – 8
350 – 6
500 – 3
144, 250, 0 – 50, 200, 350 or less, 700 – 900, 100 all received one vote (7)
No opinion - 4

Richwood - same wolves (8)
1034 – 2
1200 - 1
900 – 1
No opinion - 4

Richwood – more wolves (6)
1200 – 1
1500 – 1
No opinion - 4

Richwood - No opinion (15)

Alvin – less wolves (16)
300 – 350 – 5
Zero – 4
350 or less, 250 – 350, 350, 100 or less, 500+ - each received one vote (5)
No opinion - 2

Alvin – same wolves (2)
1200 – 1
No opinion - 1

Alvin more wolves (3)
1500 – 1
1000 – 1
No opinion - 1

No opinion (1)

RESULTS - EXPERIENCE WITH WOLVES AND KNOWLEDGE OF CONFLICTS

Within groups that chose "less", "same", "more" and "no opinion", varying degrees of knowledge and experience existed. There may be some duplication in responses as a person could have checked a level of experience and a level of knowledge of conflicts on the same survey. Some examples of how experience related to choices are listed below.

Town of Richwood - of the eight people who selected "zero" for a wolf goal, 7 had no direct experience with wolves. Fourteen of the people who wanted "less" wolves also had no experience with wolves. Richwood by far had the most surveys indicating no experience with wolves (34). It also had by far the most people with "no opinion" (24.5%) over twice the other towns. Of the 15 who had no opinion, 12 had no experience with wolves and none indicated they knew of any conflict situations in their area.

There is a large difference in respondents indicating they have no opinion between the 4 towns with wolf presence and the town with little wolf presence (Richwood). One quarter of Richwood folks had no opinion, while the other towns had largely made up their minds, with Hansen at 6.7% no opinion, Alvin 4.5% no opinion, Russell 11.3% no opinion, and Maple 12.2% no opinion. Once people's attitudes are formed, it is difficult to change minds.

In Maple, 7 of 12 selecting "no opinion" had no experience with wolves and were unaware of any conflicts. Of Maple residents who wanted "less wolves", 50 had some or a lot of experience with wolves and only 3 had no experience.

Of the Russell residents who wanted "less wolves" only 4 had no experience with wolves while 40 had some experience or a lot of experience, and 25 were aware of conflicts. This is an area where few documented conflicts have occurred.

Town of Hansen – of the 91 respondents who wanted less wolves, only 2 had no experience with wolves. Forty-two had experienced multiple contacts with wolves, wolf tracks, howling, or a combination of these. Seventy indicated they were aware of conflict situations that had happened to them, their family, or other residents in their town.

In Alvin, all respondents had some experience with wolves or awareness of problems except two who chose “less wolves” for their preference.

In general, the choice of more wolves or no opinion was associated with no experience with wolves. In Hansen 2 of 3 wanting more wolves had no experience with wolves, and ½ (4 of 8) with no opinion had no experience with wolves. Russell was similar with ½ the “more wolves” group having no experience and 4 of 9 “no opinion” having no experience. Of these two choices, only one was aware of conflicts in their Town.

DISCUSSION

The general results of these five rural towns indicate a high level of desire to see the wolf numbers reduced. The most popular goal number in Russell, Richwood, and Hansen was zero. In Maple and Alvin, the most popular goal was 350, the current goal. 350 rated highly in every Town, coming in second in Hansen, Russell, Richwood. Zero for a goal rated second in Maple and Alvin. These numbers indicate a high level of support by rural people for wolf population controls, even in areas where wolves have not been active, and even in areas the department considers to be prime wolf habitat.

As in many other surveys, this rural opinion survey again documents that experience with wolves and knowledge of conflicts decreases acceptance of Wisconsin’s wolf management.

What happens when the general population in wolf areas does not support the current program? That question is not within the scope of the current survey. However, as previously noted, experts throughout the years and world-wide recognize that for a wildlife management program to be successful, the people most directly impacted must be in support of the program. In spite of Wisconsin boasting of its wolf management success, these results do not support that concept as legitimate. More wolves does not = a better wolf management program. Quality of life counts more.

What do the wolves want out of life? I posed this question to a high level DNR manager. It was obvious that he never had considered this question. Do the wolves want to inhabit marginal or unsuitable territories? Do they want to be forced, by uncontrolled numbers, to occupy substandard territory and as a price, suffer the human-caused mortality that all experts agree accompanies occupation of human-dominated landscapes? These are questions I hope this research helps explain.

A former, well-liked wildlife manager in my area who retired was quoted in the newspaper giving this advice: “If the people don’t like what you are doing, it won’t work.” The people directly interfacing with wolves are the most important in implementing wolf management. Just ask the wolves.

******

THIS SURVEY IS BEING DONE TO ASSESS RURAL ATTITUDES TOWARDS WOLF MANAGEMENT IN WISCONSIN. *All numbers are minimum at the lowest point in the wolf population.*

1. THE CURRENT MINIMUM NUMBER OF WOLVES IN WISCONSIN, DETERMINED BY THE WI DNR COUNT WINTER 2019 – 2020, WAS 1034. USING A NEW STATISICAL POPULATION MODEL, THE WI DNR ESTMATES THE MOST PROBABLE NUMBER OF WISCONSIN WOLVES AT THE LOWEST POINT IN THE POPULATION IS AS 1195 (winter 2019 – 2020). Please select your preferred wolf management option:

LESS WOLVES SAME NUMBER OF WOLVES MORE WOLVES NO OPINION

2. THE WI DNR WOLF MANAGEMENT PLAN, CREATED IN 1999 AND REVISED IN 2007, APPROVED A WOLF MANAGEMENT GOAL OF 350 WOLVES. THIS NUMBER WAS SURPASSED IN WISCONSIN IN 2004. Please share your preferred wolf management goal or select no opinion:

PREFERRED MANAGEMENT GOAL OR RANGE OF NUMBERS:_____ NO OPINION_____

TO UNDERSTAND YOUR EXPOSURE TO WOLVES, PLEASE SELECT ANY OF THE FOLLOWING TO DESCRIBE YOUR EXPERIENCE WITH WOLVES:

_____ I HAVE NO EXPERIENCE WITH WOLVES

_____ I HAVE SEEN A WOLF, TRACKS, OR HEARD THEM HOWLING

_____ I HAVE SEEN MANY WOLVES, TRACKS, HEARD HOWLING

_____ I AM AWARE OF INCIDENTS WITH WOLVES THAT HAVE HAPPENED TO ME, MY FAMILY, OR RESIDENTS IN MY TOWNSHIP.

THANKS FOR RETURNING THE SURVEY IN THE ENCLOSED SELF-ADDRESSED STAMPED ENVELOPE. YOUR RESONSES WILL BE ANONYMOUS AND WILL BE PROVIDED IN COMBINATION WITH THE RESPONSES FROM YOUR TOWNSHIP. IF YOU DON'T CARE TO PARTICIPATE, I WOULD APPRECIATE A RETURN.

THE RESULTS FROM THIS SURVEY WILL BE SHARED WITH WI DNR STAFF, POLICTY MAKERS, THE NATURAL RESOURCES BOARD, AND ACADEMICS AND RESEARCHERS IN THE FIELD OF WILDLIFE MANAGEMENT.

FOUR RURAL TOWNSHIPS WERE CHOSEN FOR THIS SURVEY TO REFLECT THE OPINIONS OF THOSE PEOPLE MOST EXPOSED TO WOLVES OR POTENTIALLY EXPOSED TO WOLVES. ANOTHER PUBLIC OPINION SURVEY WILL BE DONE BY THE WI DNR THIS SPRING ON-LINE, AND A PREVIOUS SURVEY OF PUBLIC OPINION DONE IN 2013 IS AVAILABLE ON THE DNR WEB SITE.

IF YOU HAVE ANY QUESTIONS OR CONCERNS, PLEASE FEEL FREE TO CONTACT ME AT HOME, LAURIE GROSKOPF, TOMAHAWK, WI [redacted]

ANY ADDITIONAL COMMENTS OR EXPERIENCE YOU WOULD LIKE TO SHARE – FEEL FREE TO USE THE BACK OF THE SURVEY. 3/2021

TOWN OF HANSEN SURVEY COMMENTS:

I have livestock and they harass them all the time. I haven't had any killed YET by wolves but I have many friends that have. I think there should be a few up north and that's it.

Keep up the fight.

I just wanted to say that the DNR counts are way off in my opinion. There is no way that hunters could kill 20% of the population in less than three days. I have had multiple wolves on my land in the last year and I have seen pictures of 10 wolves on one picture from a friend's trail cam overlooking a food plot. I am not making that up, there were 10. So anyone who believes that there isn't a problem doesn't spend any time in the woods. (name and address withheld)

As a teenage girl who hunts, there are already a lot of challenges one has to endure. I did not think there would be a problem when I wanted to hunt the rut during bow season. 10 minutes into the hunt, I started to hear howling. Before I realized that it wasn't just my neighbor's hunting dogs, it was probably 150 yards away. I ran out to the truck, bow in hand, as fast as I possibly could go. 5 minutes after I arrived at the truck, a wolf popped out of the woods less than 100 feet away from me. This was my first experience with seeing a wolf in those woods. They had been in there for years. Every year, without fail, we would see them on our trail cameras. Some of these experiences have terrified me. The more we manage the wolf number, the less scared others may be to go back into the woods to pursue hunting, a family tradition in Wisconsin for many generations. While I understand many think we have overkilled wolves, I feel that if the limit was reached in two days of hunting, estimates may be a little bit off. I am very educated on this matter as I go to a very good natural resource school.

I had a wolf at the end of my driveway when garbage containers was put out. Scary. Also, one on the other side of my garage. I used to walk everyday, but don't consider it safe anymore.

Our fathers got rid of the wolves. As they serve no purpose, also are you sending money to the state to help pay for all the damage wolves do?

I can't think of one reason why I have to fear for my dogs' lives every time I put them out at night.

Our forefathers had a bounty on them for a reason. I feel there should be less than 100 in the state.

In the spring of 2019, we had a calf with substantial wounds on the side of his neck and hind quarters (gaping wounds). USDA came out and confirmed it was a wolf attack. On separate

occasions, we had a neighbor who lost several sheep in wolf attacks and another neighbor also had a calf attacked by a wolf.

As a livestock producer in heavy wolf country it is only a matter of when, not if, they find my cattle. The neighbors lost all their sheep to wolves and the DNR did nothing. It's time the DNR allows for ag damage tags to us producers that lose our livelihood to a government dog!!

Killed my dog in my yard.

The DNR is not being honest about the number of wolves in the state. I hunt coyotes, bobcat, and coon in a four township area in central Wisconsin and the number of wolves here is unbelievable and they try to say there is only around 1200 in the state. I believe 2400 is closer to the truth. I don't trust the DNR at all!

I have read or been informed that one wolf will kill, on average, 30 deer per year. I do not know how accurate this number is, but if it is accurate, that would be approximately 36,000 deer per year killed by wolves per year or an average of 500 per county. These numbers are not even close to accurate, just wonder if there is any reason for concern. Thank you for this survey.

My next door neighbor has (had) raised prize winning sheep for decades. His flock, number over 20, were completely killed in one night by wolves. There was no compensation. The children were devastated. Thank God they were not injured.

Our dog has been attacked twice!!

We can no longer walk our Woodland trails safely. Must carry a firearm! Have a horse with high voltage fencing around him. Still see wolves up close around the buildings! Have lights! We keep a shot gun with 00 buck loaded and ready at all times! Wolves are no longer afraid of humans, they cross our yard!! We live close to the family who lost their sheep to wolves. About 5 miles! We are seniors who love the outdoors and used to hunt deer, we can no longer hunt or enjoy our woodlands, or any state park trails! Children in our neighborhood can no longer play outside or ride their bike safely! We may need to fence all of our property with high voltage fence which is only way we can safely walk with our dog. We have 72 acres. Our neighbor's dog was killed by a wolf!

Numerous times I have heard 3 different wolf packs howling @ different locations.

Issue with coyotes in area. Deer population is decreasing due to coyotes killing them off. I know people say it is nature taking care of nature when coyotes kill deer. Some nights it sounds like they are killing their prey right out our back door. We don't hunt and I know they opened up for hunting coyotes and I think they, like wolves, need to be decreased in population. Need safety for our pets, etc. so we can let them roam in our yard and not fear of an attack. Thanks for allowing us to give you our opinion.

I am 74 and have always spent a lot of time outdoors. I saw exactly 1 wild wolf in Wisconsin before 1990. The estimate of 1200 wolves in Wisconsin is ridiculous. Probably twice that. Why does the DNR always over-count deer and under-count predators?

Our township has seen way too much carnage left behind because of packs of wolves. One neighbor had her dog killed. Another neighbor had a calf destroyed. Yet another neighbor had 13 sheep slaughtered. Last summer our teenage grandson and a couple of friends were camping in a tent a short distance from our barn in a little wooded area. In the morning, they told us that 2 wolves were within 20 feet of the tent. It sickened us so much. That was the last time they camped out.

They are nothing but killing machines.

Good management is a key to wolf control. Over the years, have only seen 1 wolf in my area that was about 6 years ago.

No wolves below Hwy 64. A friend lost a number of sheep to wolves. This is farm country. Landowners below Hwy 64 should be able to protect their livestock.

I have no issue with the idea of having some wolves around but the number of them allowed now is a pile of B.S. Let's keep pouring money into elk program so the [redacted] wolves have even more protein available to them, rather than rabbits and mice. Wish I knew who is allowing this to go on and why??? I admire your time and work you've put in to this issue. Thanks for your efforts!

Have seen about 6 wolves in the last 10 – 12 years. Always single, never multiple. Always on dead run or jog. Never stalking or prowling. This area has many coyotes. Name withheld.

TOWN OF MAPLE SURVEY RESPONDENT COMMENTS

Better management needed as wolves have killed large amounts of livestock and many not being compensated!

The packs in our area are having a large impact on the deer population and domestic animals too. We lost our older dog last Feb. to wolves – she had two pucture wounds on either side of her neck. She didn't recover.

Too many deer.

Several years ago I encountered a lone wolf while cross-country skiing behind my home. This year, I have seen several wolf tracks.

<u>Share the earth!</u>

Way too many wolves – cattle/livestock have been killed or badly injured. A pack of wolves, teaching their young to kill, will wipe out deer yarding up in heavy snow winters – not even eating them – just killing the entire group!. Happens near Lake Superior sometimes – I've seen it…or the remains of an attack. The wolf is a beautiful animal but there needs to be a huge reduction in their numbers in Wisconsin.

Less wolves = more deer for me to eat. Thank you.

A pack lived behind my parents home. Even came into the yard while they were working in the garden. They were snarled at and told by DNR to carry mace.

I just feel there is too many now.

No transplants. I have had bears and wolves and coyotes in my 40 acre woods. I feed cracked corn but only in limited amounts that can be cleaned up. I deal with wolves and bear by surprising them with banging frying pans together, and running towards them. I have seen a lot of does, but not a buck in three years. Land owners should be given a doe stamp (1) Too many does, not enough bucks. Don't make the same mistakes DNR did years back – bucks only – for too many years.

Wolves are sacred and should be respected – only killed as a last resort.

We need wolves. Not over populated, but enough to control other wildlife that can be a nuisance (problem).

They have killed many of my cattle, have made my farm a nightmare.

Why are we so far above the original goal? I have had them answer my coyote call – with a howl! Very close – too close.

No wolves.

My son and grandsons run a beef cow/calf operation in Douglas County. They have sustained losses every year since wolves were reintroduced. Last year, I believe they lost 16 animals – reimbursements do not ever actually cover their losses. My wife has returned home at night to find a wolf between her and the house. She had to wait it out in the car before she dared to walk to the house. Another incident at the farm was to find a cow having her calf with the calf half eaten with the calf still half in the mother. So, that said, the wolf population needs to be reduced. They find cows and calves easier to catch and kill than white tailed deer. They also had an impact on bear cubs.

If the people in Madison who think they know something about wolves would reimburse famers for their losses, there wouldn't be a problem but farmers are not reimbursed

adequately. Releasing wolves in farming communities is idiocy. The people who want them clearly don't know where their food comes from.

I am aware of wolves in my area. In fact, I'm afraid to walk the dog after dark. Wolves have been in my yard. Less wolves would be my preference!

Wolves and hunters compete as top predators. They depress the numbers severely in local hunting grounds in transient fashion. They have high hunting success.

I do a 9 hour grooming run every week for a snowmobile club. I have seen wolves on the trail but not very often. I do see tracks quite regularly though. If they're bigger tracks, like the size of my fist, I take notice. Not every year, but I have run across kill sites. Messed up the whole width of the trail. No guarantee it is a wolf kill but was deer hair on the trail.

During hunting season my family that were hunting seen wolves chasing deer. There don't need to be that many wolves. My brother and I did not get deer this past year because of them. I don't want to see any in northern WI. He has had them raise havoc with his cows also.

The Famers have had a lot of cows and calves killed by wolves, including our farm. People have lost dogs killed by wolves. DNR has tried to help some farmers but nothing they have done has worked for many farmers. There are too many wolves and they should be gotten rid of.

Thank you! For requesting the opinions and experiences of the people living in the wolf habitat areas. I own a large farm. Daytime wolf sightings are common place.

Wolves are here to stay in WI which I have no problem with. Our DNR need to talk to us hunter and trappers and get out of their fantasy world. My family and I run a bear guiding service, where we run bear baits in Bayfield and Douglas Counties. I can assure you there are at least 1000 wolves in these 2 counties alone. I personally have seen hundreds over the past 3 or 4 years. We need to have a season and manage them, not for 2 or 3 days in the spring – ridiculous.

The wolf population has far exceeded what is appropriate. These animals are destructive and dangerous to the cattle and children.

I would prefer to have the state in control of wolf management. However, I have some qualifiers that need to be addressed by the DNR. We need a science-based wolf management plan that reflects the viewpoints of all stake-holders. Wyoming does not allow dogs in the chase, both night hunting and electronic calls are not allowed, I believe. We need strict registration requirements. Personally, I would like to see tighter trapping restrictions as well. As an aside, a farmer friend of mine lost a calf to wolves this past winter. The DNR reimbursed him $600. His comment was "I should start raising bear dogs, I'd get $2,500 instead if I lost one." I hear a lot of anger and frustration over that one issue.

One cow was killed on my grandson's property last summer. As I was walking north on _____Rd. where I live, about ¾ mile from the house, I had a stand off with a wolf, waving my hands and yelling at it. Didn't seem to affect him. He showed his teeth and looked angry. Finally it walked in the woods. Its almost like they are not afraid.

I typically run 10 – 15 trail cameras throughout the year all around Bayfield and Douglas Counties, and in the early 2000's a wolf picture was very rare, so rare it was very neat to capture one on camera. In the last 5 years, it has gotten to the point that I can count on nearly every camera having a picture of at least one in not several wolves on it. Over the years, I have had several encounters with them and some area packs have become so bold in showing their presence I have removed cameras and gave up hunting/scouting all together to avoid conflict. We also have to keep our dog on a lead at all times and keep a close eye on her when we let her outside after dark. I know of several people who have had dogs attacked either in the woods or in their own yards over the last few years. Several times we have been woke up by them howling and tracks show they have been within 8 feet of our home. I'm not saying I would like to see them eradicated by any means. But we need to get the population back down to a more easily manageable number or I fear they could easily spiral out of control, which I feel they are doing currently. Thank you.

I would like to see all wolves killed off. They killed deer hunting for myself and everyone else.

They need to be managed at the state and local level!

No transplanted wolves in Maple!

TOWN OF RUSSELL RESPONDENT COMMENTS

I think trappers should get a chance @ wolves before dog runners fill all permits. Also, a area that gets a quota of 5 wolves gets 5. Not 3 and shut down because other areas shoot more in their area and it fills up the quota for other areas. One note: I live in the woods with small animals that have to be locked up every night for their safety. Not fair for my animals just for them to stay alive.

Discussing the issue of wolves in this State is like discussing religion or politics. You will never get a group of people to agree. I feel sorry for the wolves because they are just being what they are. They have to eat flesh to survive and most time must kill. Who can blame them for that? They are a species with a complex family structure and it must be disturbing to the pack when their members are shot and killed. Owning cattle, however, I can certainly understand the anger that comes with losing a calf/cow to a predator. Or as a pet owner losing a dog. Maybe the answer is not killing, but sterilization to keep the wolf population from exploding. Good luck with the issue of wolf management. They are a beautiful animal and certainly should have a place in our ecosystem.

Get rid of all. We don't need one single wolf in Wisconsin.

They are nuisances that kill livestock and potentially take down a small child. The less the better.

I believe in a common sense hunt of wolves to keep the population in check. I also believe farmers and family should not fear wolves on their property.

I'm sending this because our Mennonite neighbors will not reply and this happened in the Township of Birch. Birch is not in your survey group. With 4 persons in the house located on Co. J, they watched 4 – 5 wolves kill a deer who was pregnant with twin fawns. The wolves ripped her apart and ate her but laid 2 fetus aside. They, they carried the fetuses with them when they were done cleaning up the doe. This is just too close to us. DNR needs to attempt to keep wolves in wilderness areas – tranquilize and move them to northern wilderness. Thank you for doing this.

The wolf population needs to find its own equilibrium. They are a native population and endangered because of the rampant killing of the past. We should be beyond such ignorance but, as the recent hunt shows, hatred and bloodlust is driving this slaughter.

Farmers and individuals should prove they are having wolf problems and then a permit should be issued. Not just blanket to kill. There are more problems with coyotes and loose wild dogs than wolves. Also, why doesn't the DNR control the bear population? That is a serious problem in our area.

Number of wolves need to be determined by someone with more knowledge than I have. My only concern is deer fawn predation.

We know of a pair and a lone male that regularly travel in our area.

I was born on a small farm in _____ and lived in Lincoln Co. all my life. I presently live in the village of _____, where we have lived since 1968. I do have acreage and a log cabin in the Town of _____, where my wife says, I spend most of my time. Having this property has enabled me to spend many hours in the woods, as do my 2 sons who live about 1 hour away. I first saw a wolf on my property about 20 – 25 years ago. One of my 40's borders a private landowner, and when he started to have wolf problems. They were after his horses. This was substantiated by the DNR agent who visited the farm. I believe we can live with wolves, but I most definitely believe they are way over-populated. I found a young doe's remains only 3 weeks ago on my property. It was a fresh kill scattered all over, and by the next morning, there was only some hair left.

Finding many deer carcasses in one area. Five in a 20 acre area of woods on private property.

My father was attacked by two timber wolves on our property in 2015.

I don't believe the DNR actually knows how to count wolves and that these numbers are bogus. But I do believe there should be a yearly season with similar bag counts as this last hunt.

I hate wolves. Kill on site!

We have too many coyotes.

I don't understand the sense behind adding another predator. Such as wolves to Wisconsin that our beloved DNR did around 10 years ago. Blaming it on the wolves migrating from Canada…. (expletive)…and to all the ones saying that the last wolf hunt was just "a mass killing" obviously doesn't live with the animals nor sees the destruction these animals do. So to end my conclusion, that nothing will come from anyway, I don't believe that wolves should be in Wisconsin Period. Our fellow forefathers as always put a stop to something that the DNR just comes back in and says it's for the better reason.

Family dogs killed. Judges and DNR personnel need to have required field trips to New Wood for at least a weekend, with their family's dogs, and let them run and bark. Judges with no skin in the game will never understand. DNR knows they should have set a goal of 500 wolves for the wolf season, reaching over 200 in 3 days. New World order lovers, who want 500 to 800 million people in the world, there is 7 billion now. If you get rid of people, then wolves are necessary to keep the deer in check. No hunter or guns needed.

If you like deer you don't like wolves. They are predators and have no population control other than humans and sickness.

Wisconsin's Feb, 2021 wolf hunt was an example of the worst management of wildlife possible. The state DNR issues a huge number of wolf hunting permits – 2380 – twice as many as typical – for a quota of 119 wolves. 216 wolves were killed in less than 60 hours! Nearly 85% were hunted down and killed by hunters using packs of dogs, which is an extremely cuel and unsporting practice (for hunting down bear as well, I might add). Why was the hunt held in February when the females are pregnant?? 45% of the wolves killed were female! I have never seen or heard of such a mismanaged hunt. The WI DNR should be ashamed of themselves! Now they are planning another "trophy hunt" in November? The Feb. hunt was scientifically unjustifiable and illegal under WI State Law. The wolves need to return to the Endangered Species status.

TOWN OF RICHWOOD, RICHLAND COUNTY

I have not seen any wolves here. One time several years ago, I saw one when we had a flood and it was standing across the creek on dry land. I read about the society of wolves and was impressed. I think they are very smart animals. Thank you for the work you are doing.

I can't imagine that Richwood Twp. in Richland Co. was one of the four townships selected. Other than a very occasional wanderer, there are no wolves in the SW Wisconsin.

I seen a wolf about 10 yrs. ago. I live less than 3 miles from the Wisconsin R. That wolf was coming off the bluffs and going into the river bottoms. Crossed the road in front of me. Got a good look at him. About 3 yrs. Ago I found a set of tracks on some land I rent. In Feb. of this year (2021) I saw 2 wolves as they were as tall as the deer they were chasing. I have lived and farmed in this area for 42 years and have seen 100's of coyotes and you can tell a wolf by the height of them. I live 3 miles north of the WI River, Richwood Township.

We have bobcats and coyotes that are hard on small game birds.

Wolves are beautiful creatures and should not be hunted for sport. I never seen a wolf before, but would love to see one. Someday, I personally would love to see these animals thrive so future generations can experience them.

They have every right to be here, same as you and I. We need to stress conservation and wildlife respect to WI residents.

My opinion is properly managed.

Wolves enough to keep deer population low. Too many deer in our area!

I feel that without a hunt to manage the population wolves will lose their fear of humans and aren't afraid to enter areas populated by humans. I saw a large, thin, very old looking wolf within 1/8 mile of our house 2 nights in a row about 1 ½ weeks ago. We see single wolves or pairs around here occasionally. There are several beef herds in the area and I occasionally hear of calves lost to wolves or coyotes, but its been awhile.

1200 or more only if I can hunt and trap. (this record selected same number of wolves)

Don't need wolves!

Wolves should be treated as coyotes are. Open season year round.

As for wolves in this area, we have seen and heard them for 20 some years and we don't need them in this area.

Do not want any predation in my animals. When I worry every time an animal is pastured, the joy of country life is reduced. Keep a <u>small</u> number of wolves in the "north country" if you want them at all. Our herd does not need to see them.

Kill them all. SHOULD NEVER HAVE REINTRODUCED TO OUR STATE.

Have enough problems with coyotes killing animals without wolves added!!!

TOWN OF ALVIN, FOREST COUNTY

I would like to see no wolves in Wisconsin.

350 or less in the state, not 350 in one county – Forest Co.

My son-in-law sees wolves at his cabin area.

I and my wife have nothing against wolves. Its great to know they are out there. In fact, they add some mystic to our great Northwoods. I bow hunt a lot and have seen far more bears than wolves. Just not out of control. Thank you.

The wolves are not the issue in our county. We have had more significant problems from bear hunters with their dogs and training than having wolves in the forest. Considering how much time we spend in the National Forest, and having experienced no negative contact with wolves, the current population does not pose any issues for us, our family, or friends. It's time to stop catering to the hunters and start considering the residents of the state and counties. One additional comment: As a resident who lost a dog due to those poisoning the wolves, its really time to re-evaluate the real problem here, and it isn't wolves.

You got a live one when you sent this to me. We are overrun with deer. I have no idea about the management goal or range, but I'd like to be near them or see one once in a while. I feel like seeing a wolf up here is about the same chance as seeing a sasquatch. How do you change the attitudes people have? People here have an irrational, vitriolic rabid attitude against wolves. No one here has sheep or cattle to get riled about a wolf predating.

<u>Too many deer, not enough wolves.</u>

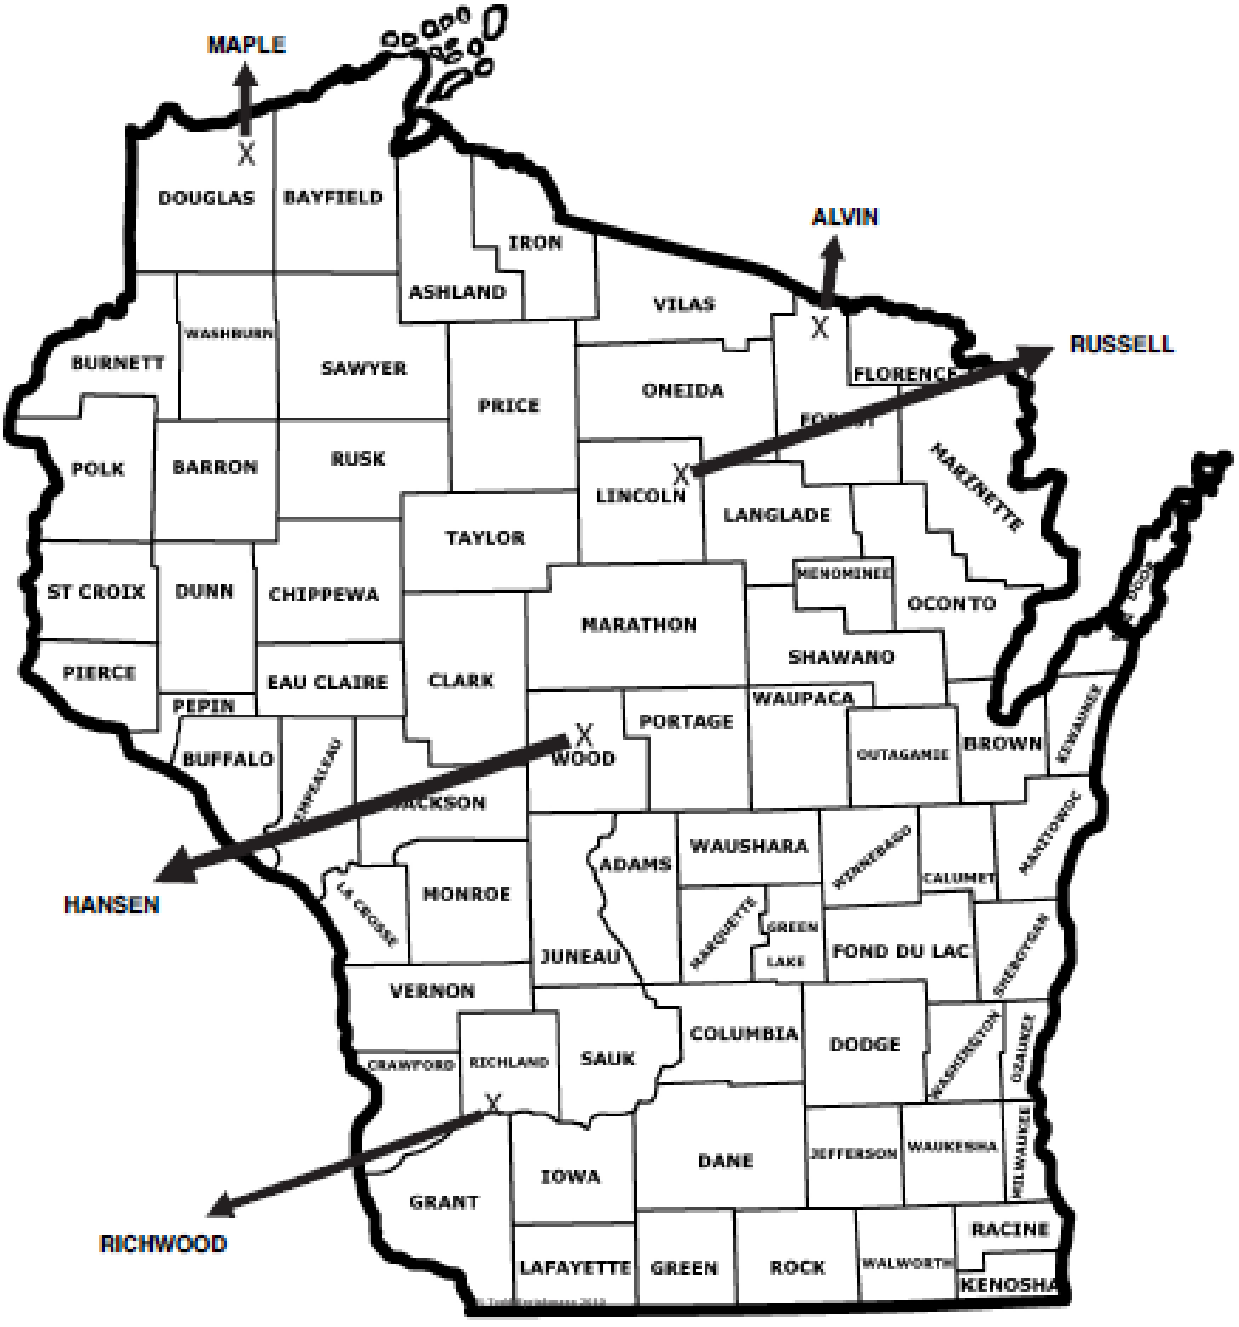
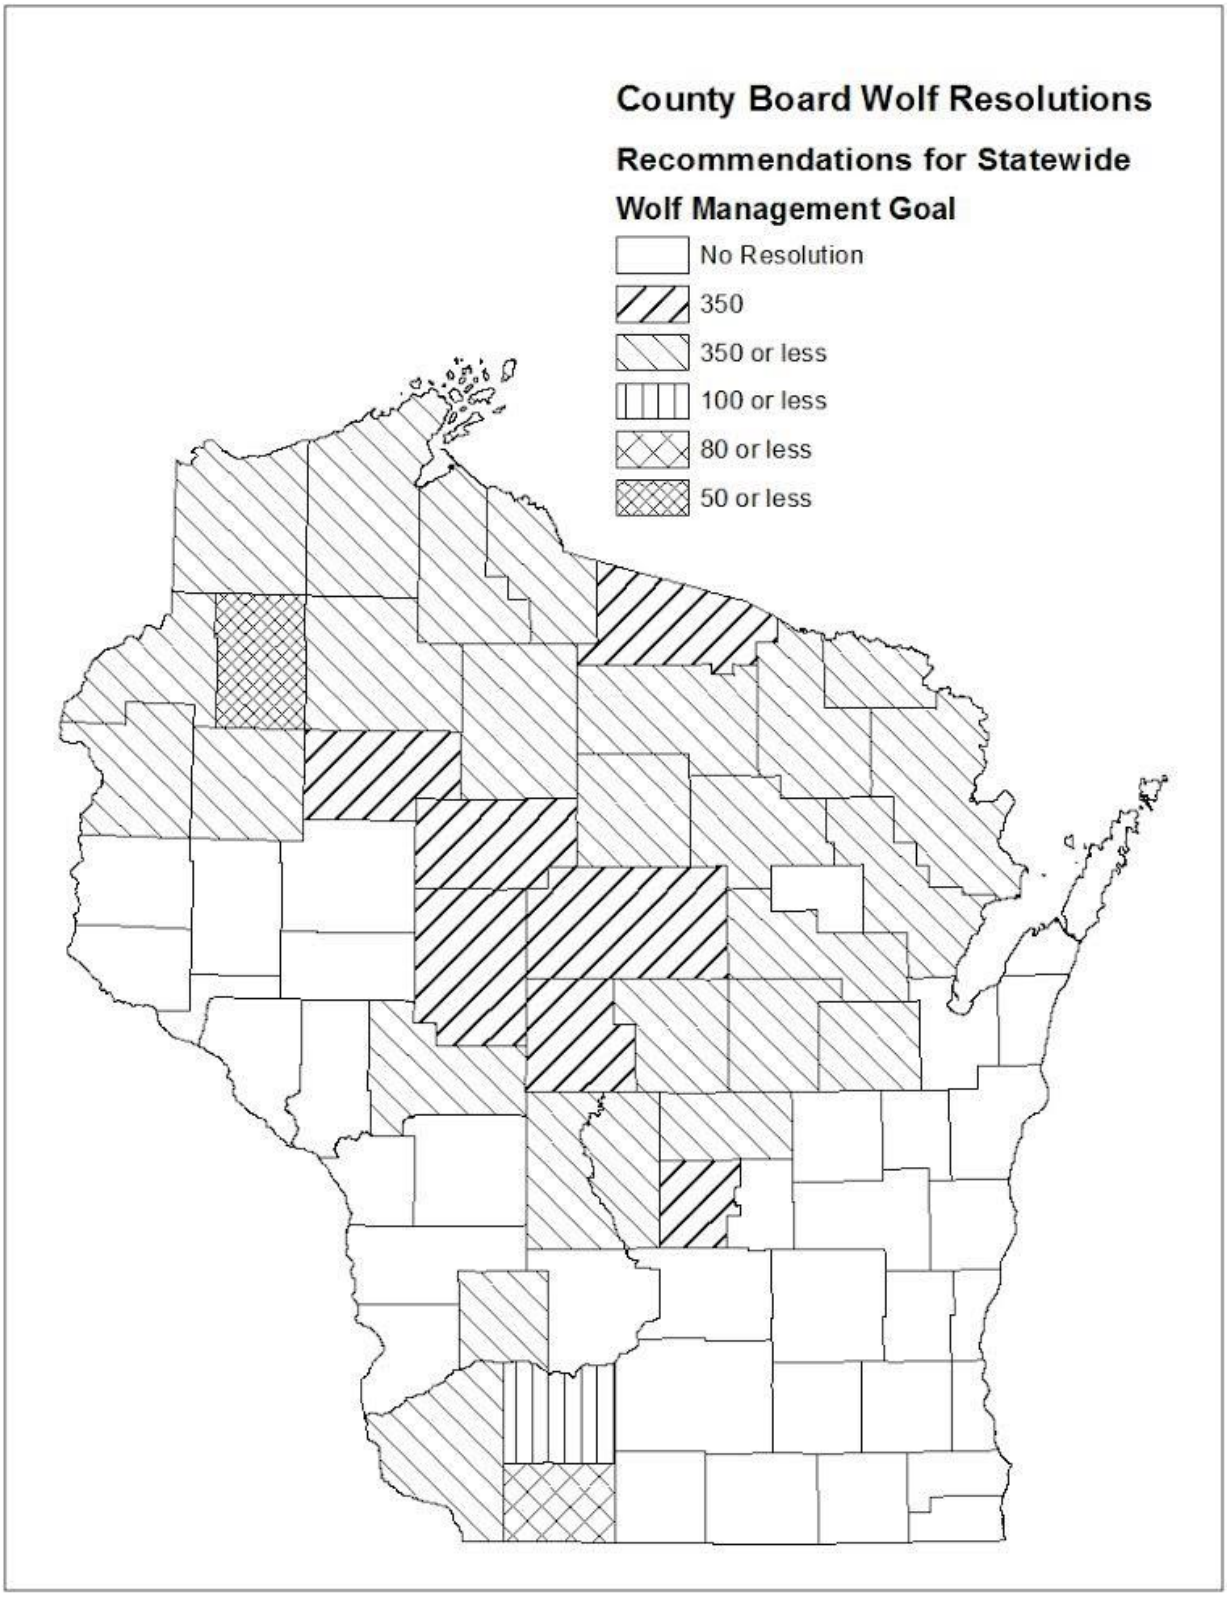
L. David Mech, International Wolf Symposium, October, 2018, keynote address

Wolf Island: Discovering the Secrets of a Mythic Animal L. David Mech with Greg Breining. U of MN Press, 2020

About the author: Laurie Groskopf has been an activist on wolf issues for over 25 years, most intensively since 2009. She has lived in the Northwoods since 1974, and prior to that, was a student at UW Madison , 1969 – 1971 and graduated with a B.A. in Psychology from UW Platteville in 1974.



Serving in many organizations in the past, Laurie represented the WI Wildlife Federation on the DNR Wolf Management Revision effort last time wolves were delisted.



Laurie has volunteered as a wolf tracker for the DNR for 8 winters. She was a co-creator and on the board of WI Wolf Facts, a non-profit organization which is a consortium of wildlife and agriculture groups dedicated to sensible and responsible wolf management. She also organized and worked with hundreds of citizens and many organizations to enable county boards to discuss and act on recommendations regarding wolf management and goals. Between 2010 – 2017, 36 County Boards (1/2 of all counties in WI) passed resolutions in favor of a wolf management goal of 350, 350 or less, or several counties less than that. In addition, a number of statewide organizations also enacted policy to promote a goal of 350 or 350 or less due to Laurie's work with hundreds of stakeholder and groups. As a board member of WI Wolf Facts, Laurie helped organize and run "Wolf Summit II" and arranged for 7 videos to be made (posted on their web site) giving farmers and hunters a chance to tell the public about their personal experiences with wolves.

Twenty-two years of survey work gathering information for USDA, DATCP, ERS, and other federal agencies have taught Laurie the complexities as well as simple usefulness of public surveys. In addition, Laurie has worked in public information including training by EPA, done outreach with UW Madison School of Medicine and Public Health, served as Planner/Program Coordinator for community-based elderly programs in 17 counties in northern WI, and run a number of non-profits.

Laurie has attended many major wolf conferences and spoke at the Mid-West Wolf Stewards Conference in Minnesota. She also attended a college course offered at the International Wolf Center in Ely, MN.
Laurie lives in rural Lincoln Co. with her retired hounds and very supportive hunting partner, who is just about the best tracker in Wisconsin and the best friend and most experienced outdoors person a Northwoods lover could ever ask for.

USING HARVEST DATA TO DETERMINE ACCEPTABLE HUMAN TAKE OF WOLVES
Prepared by Laurie Groskopf, 2/13/17

Background

In designing Wisconsin's first three wolf harvest seasons, the stated goal was to begin to reduce the wolf numbers toward the existing statewide population goal of 350, as measured by the overwinter minimum count. Data from two sources were used to determine what total human take would result in stable wolf numbers, and what total human take would reduce wolf numbers. Total human take includes all harvested animals, animals taken in control actions, hit by vehicles, illegal take, and rare other events.

Two sources were used: Layne Adams study of wolf harvest in Alaska, and a compilation of many studies done by Fuller (see Mech and Biotani, 2003). The Adams data showed a stable population would be obtained by a human take of no more than 29% of the minimum count. The Fuller studies were all over the board, but boiled down to a 22% human take being the stabilizing number. Therefore, WI DNR picked harvest quotas between 22 – 29% for the first three harvest seasons' take, minus other human take such as lethal control actions in response to depredations and the other human take mentioned.

Wisconsin's first three harvest seasons

In the spring of 2012, the minimum wolf count was around 820. Based on estimates of how many wolves would be dispatched in depredation controls, and other human take, a harvest season in the fall of 2012 resulted in 117 animals taken. Total human take was 239.

239/820 = 29%

The next spring (2013) the wolf count was essentially unchanged at 809 minimum. The WI DNR chose a harvest number which resulted in a harvest take of 257. The total human take was 364.

364/809 = 55%

The next spring (2014), the wolf count decreased by 18.4% to 660. The WI DNR made a decision to reduce the harvest for 2014. Post delisting US Fish and Wildlife Service rules state that any reduction of 25% or more would cause US Fish and Wildlife Service to do a review. The review meant they would ask WI if we were attempting to reduce the wolf population. Since our plan has a goal of 350, and since the WI DNR consistently said we were going to attempt to reduce the wolf population there wouldn't have been any sanctions. But DNR decided to reduce the wolf harvest anyway. The 2014 resulted in a harvest of 154, a total take of 222.

222/660 = 33.6%

The next spring (2015), the minimum wolf count was 746, an increase of 12.5%. As you know, wolves were relisted, and no harvest occurred in the fall of 2015. In April of 2016, the minimum wolf count increased to 866, an increase of 16%.

So it appears from Wisconsin's three wolf harvest season experience that total human take of 29% and 33.6% were not enough to reduce the wolf population. The only year the stated goal of reducing the wolf population in WI was achieved was 55% total human take in 2013.

What about Idaho and Montana?

When Wisconsin had its first season, Idaho and Montana had only conducted wolf seasons in 2009 and 2011 (they were relisted during the 2010 season). Since then, we have the benefit of 6 years of seasons in both states. How has total human take influenced their wolf numbers?

IDAHO

Year	wolf count	harvest	total human mortality	%
07	764	0	78	10%
08	849	0	153	18%
09	856	135	275	32%
10	777	46*	144	18.5%
11	768	200	296	38.5%
12	722	329	425	58.9%
13	684	356	473	69%
14	785	256	360	46%
15	786	256	358	45.5%

Wolf count is adjusted, not original in updates. *season ended due to relisting. We can see Idaho has essentially not changed its wolf numbers even with substantial harvests. Total human take in some years is up to almost 60-70% of their count.

MONTANA

Essentially, the story seems the same in Idaho and Montana.

2015	536	205	270	50.4%
2014	554	213	301	54.3%
2013	627	231	276	44%
2012	625	175	304	48.6%
2011	655	121	203	31%
2010	560	0	132	23.6%
2009	525	68	242	46.1%
2008	497	0	142	28.6%

We now have current hard data from the continental United States, including Wisconsin, from which we can design a harvest to bring us to the existing wolf management goal.

notes

I think the wolf population should stay around the 350 mark which it was set at. We see wolfs on a regular basis.

Mark Gustafson

Dennis Gutsmiedl
[redacted]
Oshkosh, WI 54904

land owner
in price county

(1) Do not know why the DNR is playing games with the people up north and the land owners up there

(2) try to sell land up north in the winter when people walk it and say no to many wolf tracks

(3) Just settle the numbers game. You said 350 make it that or even 400 I think everbody up north could live with that <u>because we are the ones that realy have to</u>

(4) This should have been done many years ago I am 65 the way the DNR is handleing this I will be dead or not hunting when the wolf population is were its shoulb be

Thanks Dennis Gutsmiedl
Do it right

Wolf Management Plan Comments

I live in Vilas County where wolf density has increased; often causing low deer numbers.

Northern counties Iron + Vilas have severe winter indexes. When coupled with wolf predation, deer just can't make a sizable population.

- There are more wolf tracks than deer tracks in some of the areas where I trap
- I find dead deer on my travels - often with broken bones (only a wolf can break those bones).
- The hunting community has been ~~been~~ hunting community to the south where deer density are higher.
- I have lived here my entire adult life - The last 10 to 12 years has seen the population drop yearling
- Remember, up north a fawn will not have a fawn until they are a year and a half - Not so in southern Wisconsin

We need a strong wolf control program - Hopefully the 350 proposed number will be adopted

RE: **Wolves in Wisconsin – Reactions to the Wisconsin Wolf Management Plan - 2022**

To the Wisconsin Department of Natural Resources:

A few thoughts from a concerned Wisconsin citizen, landowner and hunter:

1. The full draft Wisconsin's Wolf Management Plan 2022 (the "Plan") as prepared is thorough and provides information over a broad diversity of views on the topic. It reads like a masters or doctoral thesis, with context and data upfront and conclusions and summary after 96 pages of content, then 40 pages of conclusions with no summary.

   I am doubtful that many concerned stakeholders will read the management plan to the end. Maybe that is what the collective team of writers intended.

2. I take issue with some of the report's supporting methods and resultant conclusions.
   a. The Indian nations clearly have expressed and obtained zero harvest zones per their wishes and treaty rights. Additionally, by treaty they have set aside harvest values for which they can decide to harvest or not. This needs to be taken into account when harvest goals are set to achieve management objectives.
   b. Landowners and Farmers should be given similar consideration/deference in weighting the survey polling response and evaluation. Afterall, these are the people who interact/have day to day exposure to the wolves. Respondent residents in the southern half of the state, who live in cities and villages do not have the same exposure as those that reside on farms and homes in the countryside in the northern half. Many farmers and landowners in zones containing wolves, if given a choice, may prefer fewer or zero wolves on their land and adjacent areas. We should refine the surveys so their opinion is more clearly known, as they are more directly impacted by the management plan than others.

3. Wisconsin 2011 Act 169 was s. 29.014(1), Wis. Stats provides/requires the state to hold hunting seasons when permitted by listing status under ESA. As a game species to be managed by state and federal guidelines a management plan is required. Furthermore, the legislature directed the DNR to update the Wisconsin Wolf Management Plan in part to provide for a speedy implementation of hunting seasons as required by the 2011 Act 169 in the event wolves again were de-listed and came under Wisconsin management control:
   a. This report clearly provides much content and high level and broad conclusions.
   b. However, <u>it does not meet the requirements as intended</u>, by the legislature nor the citizens, to include specific conclusions should the wolf be delisted, as to what quantity across the state, or in any of the zones as established by the draft plan would be

d. We have a lack of trust towards Federal Government oversight of Wolves. We experience judicial interference by judges in courts over procedural technicalities established by disinterested bureaucrats, and without geographic jurisdiction over Wisconsin. Matters concerning listing or delisting the wolves should be decided locally by the proper authorities having governance over the citizens and land in Wisconsin.

7. I also strongly support non-lethal means to control wolf population levels. I recommend the export of Wisconsin wolves to any part of the USA that wants more of them. We should trap and relocate to them Milwaukee and Madison WI parks so our downstate wolf supporters can enjoy them in their local environment and closer to home as well as Chicago IL, New York City NY, San Francisco or Los Angeles, CA, Washington DC, Detroit MI, Oregon, or anywhere folks want them to better manage their distribution and aid in their recovery in those locations. I recommend relocation to local parks with high undergrowth density for cover. These critters will thrive and multiply quickly for recovery. We have plenty of extra breeding stock beyond our Federally set biological goal of three hundred under the ESA.

8. The preparers of this Wolf Management plan and their managers should receive administrative and professional admonishment, punishment, up to and including consideration of termination and if appropriate, civil and criminal prosecution and penalty for their purposeful, deliberate wasteful misuse of public resources for they have woefully not fulfilled the requirements of both the administrative and lawful requirements as set forth by statues. They have deliberately expended taxpayer provided resources and not delivered a required Wolf Management Plan that would include actionable specifics as required by statue.

As you can tell, as a concern citizen, hunter, land owner, that your long term inactions, lack of transparency, avoidance of the requirements of laws enacted by the citizens of the state, and citizens that share my feelings and opinions, that we no longer trust that you will act in accordance with the laws of the state, nor in the interests of the majority the stakeholders and the states citizens.

The directive was clear, prepare a wolf management plan. You have not completed that directive.

Sincerely,

Jeff Hintze

Slinger, Wisconsin

Wolf Management Comment,

I am a hunter in northern Wisconsin and I always buy sportsmans license, but I am starting to question why.

I deer hunt in the new wood area in northern lincoln county and it is getting harder and harder to enjoy the hunt. Before the wolf population grew out of control or were "plasted" we would see 25 deer or so a year on average. We would also hear coyotes way off.

Now we are lucky to see 2 to 3 deer all season and we don't hear any coyotes anymore. but there are alot of wolf tracks.

It will be harder to keep the next generation interested in hunting if they don't see deer. We have doe tags in the new wood area but they are not getting filled, they are mostly for the farm country in southern lincoln county.

I understand your hands are tied by the federal courts, but when they are not the wolf population still isn't being brought down far enough.

One of the wardens told us the wolf population will grow and

Randy Hinz
[redacted]
Merrill, WI 54452

fall with the size of the deer herd. I thought that was our job as hunters to control the deer herd and enjoy the hunt, not the wolves. I guess not anymore.

Maybe transplant some of our wolves to the southern part of the state where there are alot more deer to be controlled and see how those people like it.

I read 350 wolves was a goal, now we have over 1,000 and growing without a hunt. What happened to the 350? That is enough.

Many years ago this state spent alot of money to get rid of alot of the wolves and now they have been brought back "planted" and are growing out of control.

If the wolves are not a problem why are we always talking and fighting over them? I know wolves are not the only problem when it comes to deer hunting but they are a big problem.

I do not understand the fascination with wolves. The wolf population needs to be brought down; "Way down" <u>not</u> kept where it is now.

Wisonsin hunter.

Comments on the 2023 Wolf Management Plan

This draft plan is an excellent start to a science-based management plan for an apex predator that has re-established itself in Wisconsin. We should all be proud of what has been accomplished by the Wisconsin Department of Natural Resources, motivated environmental citizens and Wisconsin taxpayers. The references cited in the appendix are extensive and includes the major researchers of the ecology and biology of *Canis lupus.*

I completed my research of small mammals on Isle Royale National Park while at Purdue University and worked with wolf researchers during that time (1966-68). When I first came to the University of Wisconsin Center in Marinette, wolves were only talked about in the past tense. My father-in-law (LeRoy Lintereur), a career WDNR wildlife manager in northeastern Wisconsin, saw the last of wolves and would be amazed and pleased at their recovery.

The draft plan is a thorough look at the history and biology of this species, based on the peer-reviewed research of many individuals. Any one carefully reading this draft should come away with a clear understanding of the challenges that the WDNR faces managing this important species. It is also apparent that the concerns of all citizens have been considered, especially the livestock farmers. I'll list some the major points in the draft that I feel will benefit the Wisconsin wolf population; and then some further suggestions.

1. The omission of a total state-wide wolf population goal is a good idea. This **non-numeric approach** gives the WDNR the flexibility to limit hunting/trapping in parts of the state with different ecological and sociological carrying capacities. Earlier suggested population goals, such

as the 350 wolves first mentioned, proved to be far below what the environment and prey base can support. The non-numeric approach is currently used for managing deer, black bears and other species in Wisconsin and seems to have general citizen support.

2. Continuing research on wolf behavior, diseases, reproduction and sustainability are important and the draft covers these areas well. Wisconsin has a real opportunity to be a national leader in research and management of this once wide-ranging carnivore. Continuing research on human behaviors relating to wolves is also essential. Informing and persuading humans to adjust their behavior in wolf country is a challenge, but essential to reduce wolf-related impacts on farm animals, pets and hunting hounds.

3. Injuries to hounds used in pursuing wolves **should not** be paid for by Wisconsin taxpayers.

4. There should be strict limits on using dogs to hunt wolves such as number of dogs used.

5. Hound training /hunting should not interfere with wolf annual cycles of breeding and juvenile development.

6. Wolf hunting, if it is to be considered an honorable sport, should have strict limits on time of day just as deer hunters readily accept. There should be **no night hunting**, just as deer hunters adhere to as part of a hunting ethic.

7. There should be a drawing in different zones for number of hound packs that can be used.

Many of the suggestions in the report are **wisely pro-active** to avoid negative wolf-human interactions. It is important to **never again** allow such poorly prepared wolf hunt as occurred in two winters ago. The Gray Wolf is a species to be respected biologically and for some Wisconsinites spiritually, and for those reasons alone I would suggest that they are designated a **Trophy Game Species** and hunters be allowed only one harvest in their lifetime. Regulations can be crafted to allow hunters to still be involved in the hunting season.

Wolves cannot be managed without acknowledging their main prey the white-tailed deer. The cost to Wisconsinites of an excessive deer population for outweighs the cost of a recovering wolf population. The dangers to humans from deer (Lyme disease, CWD and car accidents) are many magnitudes greater. Wolves are yet another cost effective tool to reduce deer numbers.

Several other comments:

1. Depredation control and vehicle mortalities should count toward subzone quota limits
2. Use Anticipatory subzone Closure as a tool
3. More educational efforts in general and presentations **throughout the state** by wildlife managers that will provide citizens with accurate scientific information and dispel myths.
4. Fines for illegal killing and trapping of wolves should be substantial and include the loss of hunting/trapping privileges.

In summary, **the draft plan is an excellent and exhaustive start** with a fair and balanced coverage of all aspects of living with wolves. I

appreciate the opportunity to read the draft and make suggestions. Please keep me informed of the progress of the development of Wisconsin's Gray Wolf Management Plan.

TO: WISCONSIN DEPARTMENT OF NATURAL RESOURCES
ATTN: MR. RANDY JOHNSON (LARGE CARNIVORE SPECIALIST)
101 S. WEBSTER STREET
P.O. BOX 7921
MADISON, WIS. 53707-7921

SUBJECT: COMMENT FOR ESTABLISHING THE NEW TIMBER WOLF MANAGEMENT PLAN

DEAR MR. JOHNSON,

MY FIRST ECOUNTER OF WOLF SIGN SOUTH OF ST HWY 64 HERE IN OCONTO COUNTY WAS A TRACK I FOUND IN ALBRECHT LN WEST OF PARKWAY ROAD IN SECTION 8 IN THE TOWN OF BRAZEAU IN FEBRUARY OF 2019. TRACK MEASURED APPROX 3½"L x 2¼"W

MY SECOND WAS I SAW A TIMBER WOLF COME OUT OF MY HARDWOODS AND ENTER THE NEW SEEDING PLAN E 40 AC THEN S 40 AC ONTO VALLEY LINE ROAD THEN DOROTHY ROAD E TURNED N ONTO A HAYFIELD STOPPED AND LOOKED AT MY VEHICLE I TRIED TO GET A PICTURE BUT MY CAMERA'S BATTS WERE LOW. HE SURE WAS A BIG FELLA VERY WELL KEPT. MUST OF BEEN FEASTING ON A LOT OF VENISON. HE THEN WENT EAST ACROSS KULHAVER LN (DEAD END NORTH OF VALLEY LINE). THIS WAS THE MIDDLE OF JUNE 2002. HIS TRACK IN THE SOFT NEW SEEDING MEASURED 3¾"L x 2½"W.

ON SUNDAY NIGHT 9 FEB 2020 3 WOLVES WERE TRYING TO CATCH DEER IN MY YARD. DEER WERE NIBBING ON NEW GROWTH SON BITTERSWEET BUSH SOUTH OF HOUSE. WHEN I FIRST FOUND THE TRACKS I COULD SEE THAT

The 2 Biggest Wolves were sneeking Around the House walking in my tracks and attempting to surprise the deer. But they failed because of the Big snow pile.

ON Monday Evening 2 OF MARCH 2020 I saw 1 wolf Leave the Field By the Corner of my Hardwoods. That one looked medium sized and it must of Been the Smallest of those 3 that were Here in Feb 2020.

ON Sunday Eve 15 March 2020 4 different Wolves came Together in the yard close By my milk House. No Hair No Blood. I wonder why that Happened.

ON Fri Night 7 Oct 2022 the Wolves were Howly in 4 different directions at About 7 PM. I decided To See if I could Howl one in and one came Towards me really FAST But Stopped About 250 yds From me When 3 vehicles went By. "WOW" I can't Howl as good as Adrian Wydeven But one came Towards me.

ON 14 Feb 2023 at 1:30 AM When I Got Home I Heard 1 WOLF Howl To the West the Light wind was in my Favor it was Hard To Tell How Far away it was. I didn't Get it To answer me To Far I guess.

AFTER Hearing Reports From other people we've got a population of wolves Building up Here in Central and Southern Oconto County. With the Amount of domestic animals we have Here Letting the Wolves get To Heavily populated might cause A Lot of problems

IT MAY BE A good idea TO HAVE A LIMITED HARVEST HERE IF THEY ARE DELISTED. I'M REFERRING TO A HARVEST QUOTA SOUTH OF HWY 64 HERE IN OCONTO COUNTY.

THERE ARE OTHER SPECIES OF LARGE CARNIVORES HERE BUT RIGHT NOW I'M JUST COMMENTING ABOUT THE WOLVES.

I KNOW, ITS A LONG STORY BUT THATS THE WAY IT HAPPENED. IF YOU WOULD LIKE TO HEAR ABOUT THE OTHER SPECIES YOU CAN ALWAYS CONTACT ME. THANK YOU AND THE DNR FOR THE OPPORTUNITY FOR HUNTERS AND CONCERNED CITIZENS TO COMENT ABOUT A NEW TIMBER WOLF PROGRAM

YOURS TRULY,

Dear Wisconsin Dept of Natural Resources,
I am commenting on your "Wolf Management Plan" and proposing a non-lethal solution to mitigate many of the Wolf Depredation issues that continue to be filled with contentious anger on both sides of the fence. Presently, the Wolves suffer the dire consequences whether in the Western States or the upper Mid-West as Wisconsin. You should find my research WWW.FENCEFLAGWOLFTRAINING.COM posted below informative with tried, failed, and expensive scare measures intended to resolve; BUT, surprisingly continue to be used to this Date. Please read my research posting and our direct pricing to Government and identified Conservation Groups is attached for review consideration.

Attachments: RE: Mitigating Wolf Depredations

Dear Ms. Lewison,
Your posted blog in the "Washington Policy Center, 2-24-2023" received this Date, is cause for my response. The talk of "Wolf Management Plans" is certainly not unique as my **attached** suggestion to Wisconsin, with their reply, mirrors the same issues in your blog, as the resistance to stop using failed "scare" tactics continues at great financial expenses; and *Wolves continue to suffer the dire consequences.* The link https://dfw.state.or.us/wolves/updates.html to Oregon's continuing Wolf Depredation issues will show you examples of their continuing failures to mitigate Wolf Depredations. Quite simply, scare deterrents will not work if an associated non-lethal discomfort is not directly applied to the animal, or other, as a learned training to not again attempt to breach the barrier that they **VISUALLY** learned and recognized as cause for the milli-second non-lethal pain they encountered. A perfect example of failure, that continues, is the repeated use of "RED" as a color for Fladry as a scare deterrent, where with our vision and surely others, will be invisible in low light / darkness—when canine predators are most active. Please read my research posted at WWW.FENCEFLAGWOLFTRAINING.COM.

Wolf plan comments

After reading and rereading section 4 it is quite obvious the plan was written by wolf lovers for wolf lovers which Randy Johnson is one of them.

Without any numeric population goal, there is no accountability in the plan. Everything is left up to the wolf loving DNR biologist, tribes, and their wolf loving committee.

As I see it, the plan is to let the wolf population increase way beyond its current population which is way too high now. I suggest you do something to get the maximum population down to 350 wolves in the state, not letting the wolf population run wild like it is now.

Another thing the subzone around reservations is nothing but a big cop-out to the tribes. These subzones should be treated the same as the main zone. Maybe the tribes should fence the reservations to keep their wolves on tribal land. Then they would not have to worry about any of their wolves being harvested.

This is not a plan, but an insult to the people that live in the north woods. It is a farce with no intentions of decreasing the number of wolves in the state.

The December 16, 2022 issue of the Wisconsin Outdoor News has two articles in it one by Dean Bortz "Conservation Congress, WWF oppose wolf plan" and the other "Commentary" by Laurie Groskopf. You may want to read them; you may learn how people other than wolf lovers feel.

In summary, section 4 of the plan should be put in the trash can and a plan with some accountabilty and population numbers be developed.

Vern Keesler

Vern Keesler
[redacted]
Lakewood, WI 54138

Please send me a hard copy of the final plan

Febuary 27, 2023

To whom it may concern,

In my belief I do think that the new wolf management plan needs a cap number for the amount of wolfs in the state.

I also believe that there needs to be a better way to count wolfs in the state. From my time spent In the woods, I feel as if there are more out there then people Realize.

Thanks,

Alex Klein

[redacted]

To: Adam Payne, Secretary of the WDNR and Randy Johnson, WDNR Large Carnivore Specialist

I would like to compliment the WDNR for their hard work on the current draft wolf management plan especially on their willingness to focus now on **sustainability** of a changing wolf population rather than a numeric goal. Much has changed since 1999. Just as we have learned wolves do not have to be relegated to wilderness areas, but can adapt to multiple habitats, so too has science evolved with new biological principles and new research methodology. While some are stuck on the old "350" and opposed to this direction, change is inevitable. Would anyone stay stagnate with research/applied science from 20 years ago? Scientific research must continue to evolve as new information is gleaned. It is imperative to use the best available science with sound biological principles. Adaptive management is key.

That being said there is room for improvement with this current plan. In reading through the plan, it became apparent that much of the language and data reference points infer numeric goals (i.e. "quotas", "harvest" totals). How do you reconcile a harvest quota number with a non-specific population goal? While numerical quantitative data is more easily understood, in some ways it is contributing to the misconception of the old population numbers. Confusion and mistrust will be an ongoing issue given many former stakeholders may not comprehend the new Occupancy Scale Model when it's more convenient to cling to an easily understood quantitative number versus a fluctuating adaptive management process. Can the WDNR rephrase or clarify these distinctions? Former terminology such as "the goal is to reduce the population…" (pg.48) from a former wolf harvest season can be misperceived. Also, could the WDNR clarify with a more in-depth explanation on the historical context that prior population numeric goals were stepping stones as the wolf population was growing, not a maximum cap.

Other Recommendations:
A **WDNR Wolf Science Advisory Committee** should be re-established with qualified wolf/wildlife biologists and scientists.
Participant's involvement on the WDNR Wolf Management Planning Committee needs to be re-examined. There are numerous qualified stakeholders that have been excluded due to not being a non-profit. There are non-profits that represent lobbying interests with political objectives that have their own agendas. Committee members should be chosen for their knowledge of the subject matter pertaining to wolf issues and science.

Tribal Perspectives:
The WDNR's inclusion of tribal input is to be commended. Yet it may be problematic that the sovereign tribes are being instructed that – "…any contributions to this section focus on cultural relationships, history and other relevant items and avoid discussions or recommendations on policy." (pg. 38) Tribal entities should be included however much is deemed necessary by them to weigh-in on policy as well as cultural perspectives. Clarification is needed on which sections in the plan that tribes are contributing to with policy changes.

The WDNR has considered the inclusion of buffer zones (subzones 1B & 2B) around tribal reservation areas (that are excluded from the harvest areas) that must be protected. Reservation areas are considered by tribes to be refuge areas in accordance with their self-governing policies. The tribes have declared a zero quota that should be respected, not circumvented or ignored in order to increase quotas elsewhere, as some opponents would suggest. Every effort should be made to work with the tribes. The WDNR has thus proposed a low threshold harvest of 1 in conjunction with the tribes.

Re: Bear hound training / hunting of wolves:
When did the Wolf Management Planning Committee discuss at any time a "dog training season on wolves"? This appears to have randomly been inserted. As divisive as bear hound hunting is – why would the WDNR allow dog training to interfere with the wolf breeding season? While the WDNR may be legislatively required to have a wolf hunt season and implement bear hound hunting as an option, it is NOT required to have or implement a dog training season on wolves! Having a training season extend through January to the end of February, interferes with the wolf breeding season, wolf territorial patrols, wolf tracking and winter research and is NOT recommended. No other game species hunting seasons allow for interference with the breeding season or the non-stop harassment for up to eight months of the year when you factor in bear hound training (July-Sept), bear hunting with hounds (Sept-Oct), wolf hunting (Nov-Feb) all of which would allow hounds to pursue wolves. Any attempt to implement a regulated dog training season should be limited to December and close upon wolf season individual zone closures. As currently worded dog training will not close until the last zone closure. Hound training/hunting raises ethical hunting and fair chase concerns. The majority of Wisconsinites oppose dogs hunting wolves. What should territorial wolves do when the dogs catch up to them? Wolves unlike bears and cougars can NOT climb trees, but turn to defend themselves, resulting in canine fighting, and usually the death of the dog. Intentionally putting dogs at risk with wolves should not be rewarded with compensation. Canine fighting is a violation of Stat.951(08).
Act 169 needs to be legislatively readdressed. Act 169 has been detrimental to wolf management and needs to be eliminated and replaced with a new statute based on recommendations from the best available science. Bear hound hunting of wolves is unnecessary when it comes to the wolf quota. It is proven to alter wolf behavior as is illustrated by the wolf-dog conflicts and depredations already in evidence with bear hounds employed during bear hunting season. Dogs training on wolves should not be permitted as previous quota seasons have demonstrated in quick zone closures that it is unnecessary.

Transparency:
The WDNR has referenced that data is collected at every opportunity when it comes to wolf mortalities. Biological data was collected and monitored during the 2012-2014 wolf harvest season, but not during the 2021 wolf season. The WDNR should implement a return to collecting this type of data to further Wisconsin wolf research. Such policy changes will focus on having more transparency and sharing of data.

Research and Monitoring:
- Research how wolves impact CWD and benefit the health of deer in CWD areas.
- Enact a 5-year post-delisting monitoring in accordance with USFWS.
- Implement administrative rules to protect wolf den sites
- Implement research on impacts of behavioral changes on wolves from bear hounds

- Continue to research non-lethal abatement techniques in agricultural areas to support the farming community

Education and Outreach:
WDNR should implement educational endeavors to:

- Further explain the transition from Track count surveys to Occupancy Scale Model wolf population monitoring.
- Explain population monitoring efforts and wolf impacts on Wisconsin northern deer populations
- Employ cooperative social science public attitude surveys on a 5-year cycle

Correction: Pg. 131 "…engagement in live events such as forums, sports shows (e.g., *Wolf Info Now in conjunction with the Milwaukee Journal Sentinel Sports Show*),…and invited presentations has proven to be an effective strategy for disseminating information and these practices are recommended to be continued."

In summary, the WDNR has taken into consideration a multi-perspective range of diverse input in the compilation of this draft plan. Perhaps the most striking note is how the terminology has evolved from the limitations of a static numeric goal to show new research methodology in gathering data in wildlife population monitoring across changing ecosystems. Perhaps the WDNR can elaborate on how these new measures will be implemented. The WDNR has recognized its role beyond natural resource monetary gains to a role in conservation and stewardship encompassing hunting, recreation, ecotourism and wildlife watching. As the WDNR takes this forward step to bridge the gap between old methods and new adaptive management strategies, it will result in a more inclusive public process in the stewardship of our natural heritage.
Finally, I would refer the WDNR to the analysis statement by the Wisconsin Green Fire on the 2022 Draft Management Plan for additional details.

Respectfully submitted,
Gloriann Klein

NO FEAR

R.E. Public Input Regarding Timber Wolf Management.

With the caveat that I personally do not live in the distribution zone, I am in favor of allowing the natural increase of wolf numbers to correspond with their habitat carrying capacity and 'habitat' in this instance having nothing to do with human intent. It will be testament to our own evolution as a species to learn to share the land with wolves; every other native species has been forced to share with us, frankly have learned to stay out of our way at their own peril.

It's time that we strive for higher ground and acknowledge that wolves (as well as coyotes) fill a crucial ecological niche, a sturdy strand in the web of life fabric. Of course we know with settlement

and unceasing pressure since, we have torn this fabric to shreds to our own inestimable psychic loss.

With a renewed respect for wild, native restoration we should aim high and attempt to discover (undoubtedly over many years) the sweet spot where wolves meld seemlessly with the greater whole.

As to predation on 'livestock' the compensation should be distributed toward reinforcing the paddocks and fencing partioning the domestic from the wild.

In the event that the input and policy weigh in favor of the minimal then any shooting should only be done with the close supervision of state wildlife biologists — i.e. contrary to past policy only professional sharpshooters, again with thorough education, should undertake this.

Past predation occured because of random killing, the killing of alpha males and alpha females as well as the immediate subordinates resulting in severe pack disruption. The pack structure fashioned over millenia cannot be altered without consequences.

February 8, 2023

To Wolf Management Plan , planners and staff;

I want to thank the NRB and other persons who granted the extension to offer comments regarding the wolf management plan.

I am a retired technical college and UW extension Ag educator teaching post high school youth and adults for 37 years. I am a wildlife ecology graduate from UW Madison. I have hunted since I was 13 and I trapped a few years as a younger youth and two years while in high school. I have trapped regularly every year since 1980 to the present.

I am one who does not feel the lack of a set number is a bad thing. I do however feel that without a set number the responsibility and accountability ratchets up and I trust that the department has the resources and discipline to respond to the potential for increased social and ecological interactions.

I do have significant concerns with the expanding of the reservation borders into public and private land. To me we could be caught up with many lengthy private property rights that could delay any movement forward regarding putting the wolf management plan into action for the vast majority of the land base in Wisconsin.

I am also very concerned by the significant expansion of zone 4 which includes 4a as well. We have added over 200,000 citizens and 200,000 head of dairy and beef cattle into a zone that may well be managed for higher wolf populations with significantly more real potential for depredation of livestock and other human interactions. Having worked with dairy farmers for over 40 years I have concerns about managing many herds of livestock all surrounded by much higher human populations than many of the higher population zones past and present. To me there also needs to be a terminal dispatch for depredation animals. Transporting known and potential depredation animals into the existing higher population density areas of wolves to me is not good management. New wolves and in many cases single wolves take time to adjust and fit in if they ever do with territorial, pack oriented canines. The likelihood of more depredation or dispersing to lower density areas is very high in my opinion.

There are many references to sustainability as to the wolf population. Sustainability is a very subjective term when dealing with all the aspects of how a species fits into the environment and habitat that they share with not only other wildlife but in the rural and even suburban residents of Wisconsin be they farmers, non-farm rural residents or those participating in the multitude of outdoor activities that Wisconsin has to offer.

How much territory does a pack of wolves need to thrive? I feel that depends upon the cover base but also the food base and where wolves are the most common (northern 1/3rd of WI) the food base may not be limiting but there is far less edible biomass per square mile in the northern 1/3rd then in our southern portion of WI. We need to think seriously about how expansive we want our wolf population to be. There are several places in southern WI where we have thousands of acres of wildlife land surrounded by agriculture and high human populations. These areas could easily become home bases for packs that could easily find food in the agriculture areas surrounding these large wildlife areas. I would prefer not to see wolves as common predators in those regions but if we are going to let higher

densities exist in the targeted areas those younger wolves will need to disperse as that is the nature of the wolf culture. Putting seasons on any species brings resources to that species and I would hope that when the stake holders meet that a plan for a sustained harvest over 5- 10 years could be instituted and tweaked as needed. With each year of an added season we will get more data to really help us to know better the population numbers, movement trends, age distribution etc. Somewhere in the middle is probably where the interest groups need to meet and in our modern day politics being a centrist is like having the plague. We need a management plan that allows the citizens of Wisconsin to gain control and management of a significant predator to our rural and wildlife landscape.

Sincerely,

Bryce Larson

Dear Wolf Management Plan Committee:

I am writing to express my concerns with the current proposed plan.

1) The current plan has no triggers for population control. In fact, it has no metrics or triggers at all. While this may have intentionally been left out, in hoping to minimize conflict; the lack of specific benchmarks for management action makes the "Plan" not a plan at all.

2) The wolf has vastly larger home range than the Whitetail does. It is also THE Apex predator. Wolves should not be managed the same as Whitetail. Wolf depredation of deer, pets, hunting dogs, and Cattle must be minimized. I suggest reinstating the 1999 wolf population goal of 350, but if that's the wrong number, let the new carrying capacity of Northern Wis. habit changes be the guide with science that minimizes wolf conflicts.

I ask that these issues be addressed.

Thank You. Greg LeGrave [redacted]

I am a Wisconsin citizen since birth, a retired public school teacher, a lifelong learner and a conservation voter. Even though retired, I am still a teacher, without the comfort of a classroom, in educational outreach to promote peaceful coexistence with the gray wolf.

I want to commend the work of the DNR Wolf Planning Committee, in the development of the Wolf Management Plan. I applaud your conclusion to not adhere to a numerical minimum population count for the gray wolf in your report. The annual population modeling conducted by the DNR supports this decision.

I propose the DNR consider changes to the Plan in the following areas:

1. Nonlethal tools and strategies. The science is still evolving on the ecological function of the wolf and wolf behavior in the human-wolf relationship (Eisenberg, 2010). We cannot continue mass killing of wildlife demanded by one sector of our society. It is the obligation of the state agency in charge of resource management to dedicate attention to work with the agricultural sector in good animal husbandry practices, and the use of nonlethal tools and strategies followed by justified compensation for loss. Removing innocent wolves or the entire pack with the killing of livestock-killing wolves may be a

temporary solution. Santiago-Avila etal, 2018. This risks destabilizing the wolf pack, its cultural identity, and unknown wolf behavior in future predation, and public sentiment against this culling method. Bruns, Waltert, Khorozyan, 2019. Further, this study evaluates citations on the effectiveness of nonlethal measures in livestock protection.

The payoff to the DNR for establishing a relationship with the producer will come back as a reward in the form of building trust in your agency. The states of Washington, with an elaborate cost-sharing program and Minnesota's 80-20 matching grant program are possible models. A Wisconsin nonlethal approach to prevention/conflict mitigation should be adaptive, dynamic and creative. Eisenberg writes of a large ag landowner in western US who believes in gentle handling of calves so as not to injure them making them potential prey animals (Eisenberg, 2010).

I recommend the DNR consider a rule to provide sanctuary free of running dogs in a pilot wolf range, such as a federal or state public land; or closing of a site(sites) during denning season. The DNR should be studying the effects of the high volume of running dogs on young bear cubs and dog/wolf conflicts. Wisconsin citizens and out-of-state tourists can enjoy the great outdoors without the noise and intrusion of running dogs. In conclusion, I am strongly in favor of nonlethal use against wolves, except in case of serious threat to life. 2. Education/outreach. I was happy to read in the Plan the

proposal to develop education programming with a variety of interested wolf advocacy groups. McNay, 2002, makes a compelling argument for education: Injuries to humans inflicted by wolves are almost totally preventable. The goal of education should lead to peaceful coexistence, dismissing many myths surrounding this shy, hidden, forest animal.

Thank you for this opportunity to address my thoughts and values in behalf of this intelligent, social animal that we share space with.

Lois Lehmann

DeForest, Wi 53532

The following are comments on the Wisconsin Wolf Management Plan-2022, made by a deer hunter, owning and hunting land in Wolf range

My name is Paul Lelinski. Our family owns 120 acres of hunting land in northern Rusk County-Wolf Range. My comments on the 2022 WI Wolf Management plan are from the viewpoint of a deer hunter. I have been hunting the property in Northern Rusk County since I was 12, I just turned 48. I am a hunter who has seen his, and his families, deer hunting opportunities on our private land in "wolf range" diminish so significantly that we have sought out other areas in the state to hunt. There are several contributing factors to the reduced deer hunting opportunities we are experiencing. Logging or lack thereof, winter severity, and predator load are 3 large contributing factors in northern Wisconsin. We, as landowners, have limited control over different aspects of each of these. On our land we continue to improve habitat to improve our herds health and quality. We love our land. We can not move our land. We want our land to be our own hunting paradise, as it once was. Without addressing other factors, predator load (primarily wolves) continues to be the most consistent stressor on our deer population. This plan fails to show course to manage the wolf population to a reasonable, not extinct, level that will once again allow the robust deer numbers of the late 1990's and early 2000's.

Below I will list my comments on various parts of the plan that are, in part, reasons I do not support the 2022 wolf management plan as currently drafted.

I understand that the early pages of this draft are background on wolf biology as well as how we got to where we are. I found some of this information very insightful and revealing.

Additionally, while I know that there is nothing scientific about "civilian observations", there is weight that comes along with them. The DNR acknowledges that from there consistent requests to the public to contribute to many of their management programs with observations. Whereas I will use mine and my neighbors' observations as basis for some of my comments.

In the early pages of the draft the there is a discussion on trophic cascade or ecosystem services provided by wolves. The first listed is "Limiting, and possibly regulating, the growth and abundance of prey populations." As pointed out in later pages of the draft, whitetail deer are the primary prey species of wolves. The immediate conclusion is, how can we allow the wolves to regulate the prey species population when we, humans, are already doing that?? I will point out this same sentiment in other parts of the draft. This is one of my leading critiques of this plan. You CAN NOT have 2 apex predators that depend on 1 prey species! Humans are the apex predator in today's world. We can not harvest deer in wolf range as if we are the only apex predator. Either we need to limit the number of deer man harvests or MAN needs to limit the number of deer wolves' harvest. This same section of the plan goes on to discuss the "Landscape of Fear". This is an additional consequence that I have personally observed in our deer population. Even the deer that are not killed act differently. There are several different graphs in this draft that show "conflicts" of various kinds and when they occurred. I believe every graph shows the prevalence of conflicts was low in 2014. I also observed a reprieve from the "Landscape of Fear" in our deer population at that time. This was an immediate and unmistakable result of 3 wolf harvest seasons in a row. As pointed out in more than one part of the draft, Wolves have shown to be very adaptable, changing to the present environment. This was shown when they realized they were being hunted. We observed a difference in the woods. Deer moved more freely because wolves moved much more carefully. This was also observed on trail camera picture occurrence. Wolf pictures dropped

significantly at this time only to rebound when they were re-listed, and the pressures were removed from them.

In another early section of the draft there is a discussion on additive or compensatory mortality. I found this discussion enlightening and possibly a great driver to what wolf populations should be. Currently our wolf mortality on whitetail deer is ADDITVE. There can be no questioning that. In our little part of the woods, we continue to improve habitat as do our neighbors, through logging and cultivated food. This is done to offset the forest succession that naturally occurs. With that said, our deer observations have diminished greatly. If the capacity of the land is being augmented by manmade changes to maintain its carrying capacity, then deer numbers/observations should remain the same if the wolf mortality is compensatory. Since there is a decline the mortality if Additive and that is unacceptable at its current rate. I think that compensatory deer mortality should be the goal of this management plan.

Later in the draft there is a discussion about "wolf acceptance and perception". In later definitions of the plan goals, the public's perception and acceptance is used for driving goals and decision making. Whereas this early discussion needs further critique. On page 24 it clearly states that the longer people live and work in wolf range, the more negative their view of wolves becomes. This needs far greater weight than that of academics and urbanites who only study and think about wolves, and don't truly know them. There needs to be a weighted scale when considering Wisconsin Resident Perception of wolves as a driving factor in decision making. Those who live, hunt, work, in wolf range and deal with that actual effects wolves have on the ecosystem, should have their perceptions count many times over that of the perception of someone who lives in the urban areas of the state and never even travels to wolf range. A distinction needs to be made if resident perception continues to be considered. One additional note in regard to resident perception of wolves. The draft goes into great depth in several areas to explain and emphasize the importance of the grey wolf to the native American tribes whose reservations occur in Wisconsin. When "resident perception" is used to drive decision making, Native American input needs to be withheld. Their lands are closed to any wolf take. Per their treaty rights they are given a prescribed amount of harvest authorizations when ever a season is permitted. The native American positive wolf perception has been slaked through the aforementioned measures and should not have a voice when it comes to management of the rest of the states wolf population.

I am not a farmer. I have little to draw from in comment on the parts of the plan that discuss the effects wolves have on the Wisconsin Farmer in wolf range. What I can comment on is that this draft exhibits many "pro wolf" comments and directions. Almost trying to convince the reader that wolves do not have an impact on the ecosystem or that the affects the do have are all positive. This is shown on page 28 in the discussion of predation on livestock. The draft would lead you to believe that "non-lethal" measures are more effective to protect livestock that "lethal measures". I believe this is yet another "pro wolf" comment in this draft. A non-lethal measure could be construction tall, wolf proof, fences around all your livestock pastures or installing lights that keep your livestock out of the dark, as opposed to trapping or killing the problem wolves. I can understand that no wolf can get over a 10' high fence, and that if you kill a wolf, another may replace it, but is fencing all the pasture to that extent or installing lights in the fields practical. Is this something that we should expect our agricultural producers to endure because the state will not manage the wolf population as a problem? As I said, I am not a farmer, maybe I am missing something here. One additional comment when it comes to farms in wolf range, as mentioned before, people who work in wolf range need to have their feelings/perceptions weighted much higher than those who work outside of wolf range. If we compare wolf management to other species management in the state, it would seem natural that problem wolves are trapped and

relocated or euthanized. That's how problem deer and bear are handled in and around agricultural properties. Again, another example of the "pro wolf sentiment" that permeates this draft.

On Page 98 we are introduced to the plan goals. My opinion is that they are extremely broad and not well defined. They leave so much room for people to "bend" them to fit a specific narrative. I do not believe the plan goals stand on their own with out better definitions. I realize there are pages of "qualifiers" however, they are wordy and broad. An example is "ensure a healthy and sustainable wolf population". What does that mean? In earlier parts of the draft the state was originally looking for 350 wolves in order to remove protection from them. That must be "healthy and sustainable"? If that is the case, we are well past that, so we need to reduce the number?? "Fulfill their ecological role", again I don't understand. Are we talking about the historical ecological role of wolves? As mentioned before, humans are the apex predator now. While I don't think wolves should be extinct, I am not sure we missed them in the 80's when there were no packs thought to be in Wisconsin. By that I mean the rolls that the wolf plays in the ecosystem did not go un-fulfilled. Week or sick prey were taken out of the population by other predators. Human's control the prey populations now, not wolves. So, what is this plan goal driving at? Again, there can not be 2 apex predators.

As many have already pointed out, there is a glaring omission in this plan. There is no population goal and/or any metrics on how to arrive at one. The harvest strategy to either "increase, decrease, or maintain" seems ridiculous. Outside of trail cameras, people rarely see wolves. So, what would "The People" base their answer on. Perceived impacts of wolves? This is speculative at best. Are there any good impacts from wolves that people would perceive outside of a wolf hunter/trapper wanting better harvest opportunities? I don't know how anyone would answer that question if posed and civilian perception was again used to drive policy.

As I read through the plan goals, I feel like they do not do nearly enough to qualify the measures and tools that will be used to assess and manage the wolf population. It has a strong feel of a plan that does not want to manage or control wolves. I want to see some pressure put on the wolf population. Every other big game animal in Wisconsin has human pressure put on it through a harvest season. In most cases the harvest seasons are very generous. Yet in the case of wolves, when de-listed, a very limited quota is put on them. Again, "pro wolf" sentiment.

In addition, I believe that there is not nearly enough weight put into "consideration of prey populations" under the first plan goal. Wolves are the only predator species that we have in WI (outside of cougars that is believed to be a very small population) whose primary food source is another game animal, white tail deer. How can this plan gloss over that relationship? As mentioned earlier in my comments, I am a deer hunter. In wolf range, I do not believe that the whitetail population can sustain unlimited harvest by both humans and wolves as well as deal with the other, unavoidable stressors that put pressure on deer (winter weather, winter food sources, etc). It seems that the wolf population or management has to be directly tied to the white tail management in wolf range. There are even other qualifiers in this draft that discuss having enough food (deer) to support the wolf population as well as the "carrying capacity" of the landscape when it comes to wolves. That is a direct relationship to the numbers of deer. This plan does not come close to explaining the relationship between the 2. You are led to believe the deer exist to feed the wolves and that is it.

I take issue with the idea of the sub zones around the tribal reservation lands. This basically enlarges the tribal reservation and takes land away from "The People". The tribes have agreements in place that must be respected on THEIR land, not their neighbor's land.

In objective A on page 111 there is a guideline that says, “no radical changes in wolf populations”. Based on what numbers. The plan does not give us a starting point. If that is the case, I am further concerned that this is again another “pro wolf” measure. If we are to base “no radical changes to the population” based on today’s population, then I completely DO NOT support the plan. We currently have an overabundance of wolves due to the federal protections that have been in place as of late. If I am to believe that we will base this on whatever the population climbs to between now and the time management is given back to the State, then we will have an even larger population. I believe the population needs to be reduced extensively. This note is another attempt at placing verbiage in the draft that will promote or allow for a higher wolf population.

In Plan goal B it discusses compensation for wolf predation. While on the surface I agree that agricultural producers should be compensated to fair market value for their loss (I’m not a farmer so I may not have that fully understood), I do not agree that hunting dogs and pets should have a cap at $2500.00. Many pure breed pets cost well more than $2500. Hunting dogs can cost 10 times that amount. If there is going to be compensation because the state does not manage the population to a reasonable level (or can’t when wolves are listed) the compensation should be at least the value of the loss.

On page 124; Product C1d “continue to exclude reservation wolves from harvest consideration when developing wolf harvest quotas”. I STRONGLY disagree with this product. I am not even sure how “science-based management” can allow for this. The population models that are used to determine a harvest quota are to ignore certain wolves? Is that in a textbook I can read? This can not be allowed. The population is the population. “Tribal sovereignty and cultural importance of the wolf to the native Americans” is done by surrendering tags to the various sovereign nations as well as not allowing harvest on the reservation lands. To also not includes these wolves in the population estimates would result in a false population, and a deliberate, yet hidden, inflation of the wolf population. Again, another example of a “pro wolf sentiment” in this draft.

On page 125; Product C2c Zone specific tags are promoted. I disagree with this initiative. If the wolf harvest is based on zone specific quotas, let hunters go where the quota is not fulfilled. I feel like this would place an unnecessary restriction on wolf hunters/trappers. To compare this idea to zone specific tags issued for Turkey or Bear harvest is not an apples-to-apples comparison. Turkey and bear hunts are not quota driven, wolf hunts, to date, are. Again, another roadblock to reducing wolf numbers.

I further disagree with parts of this plan on page 127; Product C3a “ecotourism brought on by wolf population”. This plan is trying to make a comparison between Yellowstone National Park and Northern Wisconsin. I think this is an extreme stretch. I think this is and attempt by the writers of this plan to show some sort of “made up value” to an increased or large wolf population. To expect there will be any kind of a positive economic impact from a wolf population, other than a small one from a harvest season, is a made-up value. To make the comment that people will find enjoyment in seeing a track or scat is another attempt by the writers to try to find value that just isn’t there. To further believe that it will result in a positive economic impact is ridiculous.

Products E2b & E2c on page 133 are of paramount importance in my opinion. This plan relegates them to a mere afterthought. I think these products need to be a primary part of a plan goal. It seems, in a small way, this plan acknowledges that many activities are negatively impacted by wolf populations. Whereas there is economic loss associated with that. So many small businesses in wolf range rely on

things like deer hunters, grouse hunters, shore fisherman, campers, and hikers, they buy food, gas, lodging, etc. When those activities are reduced or moved to other parts of the state there is a large negative economic impact. That cannot be overstated, yet this plan does not give that point nearly enough emphasis.

In summary, I am a deer hunter who wants the impact of wolves in northern Wisconsin to be reduced. I do not believe that wolves should be extinct. However, I do not believe that the ecosystem needs wolves to stay in balance either. I do not believe all parts of this plan are bad or incorrect. I have made comment on the areas I felt needed to be critiqued. I support things like additional monitoring and utilizing our university system to better study and understand the wolf population. Wisconsin's wolf situation is unique in that wolf range in Wisconsin has the highest human population of anywhere in the US. This results in a large increase in conflict and issues related to a large wolf population that does not exist in other states. Further, wolves have shown, as noted in this draft, an adaptability that was not expected. Wolves continue to grow their range. The carrying capacity of what was once thought to be wolf habitat, has not limited wolf population growth. Rather, wolves have adapted and expanded their range. Since the population has not found an equilibrium and continues to grow it is time that humans limit the wolf population in consideration of all the issues and conflicts discussed in my response. With all that said, I see a plan, that I cannot support in its current draft, that uses a lot of words to try to justify a large wolf population, but then recognizes conflicts and issues. There is so much discussion, monitoring, and effort that must be spent on the different conflict issues (agricultural loss, hunting dog loss, loss of economic opportunity from reduced deer hunting in the wolf range, etc, etc.) when reducing the number of wolves would reduce the number of conflicts and thus the level of effort and money spent on such. That idea seems to be fairly simple.

WI Draft WMP Talking Points

What we like:

We appreciate the efforts of all WDNR staff involved in updating the state's wolf management plan. Although we believe the current plan needs significant updating (see next section), we recognize the efforts and improvements made to the previous plan, including:

- Wolves in WI will no longer be managed by reference to the old numerical goal of 350 wolves.
- There is much greater recognition of the ecological role of wolves
- The inclusion of a social survey, which notes increased positive views of wolves, knowledge of their ecological roles and increased opposition to the motives and methods for killing wolves
- The adoption of proposed buffer zones around tribal reservations (i.e., previously no buffer zones existed)

What we don't like:

- The current draft does not reflect the best available science, and is missing a substantial amount of scientific literature on (see reference list below):
    - wolf ethology, sentience, sapience, sociability, agency and wellbeing
    - effectiveness of non-lethal interventions, especially relative to lethal ones
    - the impact of widespread killing on wolves' physiology, behavior, wellbeing, social dynamics, ecological relationships and evolution
- The above scientific omissions, combined with the emphasis on and promotion of sustainable recreational killing and consumptive users as a main management strategy, results in a biased plan that runs contrary to scientific evidence despite much of this omitted scientific evidence being more recent, numerous and of stronger inference.
- The plan should strictly curtail any lethal management of wolves except in extremely rare circumstances of immediate defense of life.
    - A substantial body of research documenting human-caused mortality in North American wolves, including Wisconsin wolves, has found that policies allowing liberalized killing of wolves result in a direct increase in the hazard and incidence of illegal killings.

    - Hounding or hound training, which are akin to allowing legalized dogfighting, should be illegal or severely restricted as this practice is extremely cruel to wolves and hounds alike and is not supported by the majority of hunters or the broad public.
- The plan should prioritize wolf protections and concentrate solely on non-lethal management of wolves in response to livestock conflicts to ensure ethical coexistence.
    - Despite Act 169, which mandates a wolf hunting season, the department can still restrict the implementation of lethal methods by setting minimal quotas, including a quota of '0' wolves, restricting timing and methods.
    - Several studies have proven a proactive non-lethal approach leads to better conflict mitigation.
    - Lethal management often fails to provide a long-term solution to wolf predation and has the least consistent success rates when compared to non-lethal practices. In addition, there is significant evidence showing that lethal wolf management may be less functionally effective at mitigating subsequent livestock losses than non-lethal deterrents.
- The plan should *require* the implementation of abatement measures as well as the use of non-lethal conflict minimization techniques by domestic animal owners for the latter to receive compensation for confirmed predation.
- The plan also runs contrary to public values towards wolves (and omits mention of such majority values from the plan), despite department surveys evidencing that the broad public cares about wolves as individuals (and not just for the viability of the population). Given the recent liberalization of killing wolves by the state, it would be incredibly informative to note majority support of the following reasons for opposing a regulated wolf hunting/trapping season (which are all omitted from the plan): opposition to specific methods of harvest like hounds (64%) or traps (70%), feelings that hunting wolves is unnecessary (62%) or culturally offensive to Native American tribes (57%).
    - All such reasons convey majority disagreement with practices currently promoted and endorsed by the legislature and the WDNR, and such a conflict between managers and the public should not only be acknowledged, but foregrounded and carefully considered in policy (instead of dismissed).
    - Such decisions to omit literature or downplay evidence (e.g., such as majority opposition to killing wolves and their reasons) are contrary to principles of scientific integrity (e.g., present all relevant scientific evidence to the public) as well as ethics (e.g., disguising ethical decisions, such as recreational wolf killing, as robustly supported by science).
- Conflicting agency objectives (e.g., optimizing public hunting and conflict mitigation) are not only not acknowledged, but even misunderstood as harmonious, against the body of scientific evidence. That culminates in the prioritization of consumptive values and policies; e.g., according to the body of scientific literature, use of lethal methods, and

especially public hunts, are contrary to most objectives relevant to: harm mitigation, the wellbeing of wolves, their ecological roles, and their non-exploitative enjoyment (i.e., Objectives A, B, D and F).

- There is a stark lack of consideration for individual wolves, wolf population health (including wellbeing), and measurable indicators for assessing any harms barring disease prevalence (e.g., accounting for cortisol levels or other stress hormones, measures of pair/pack persistence)
- There is an inappropriate understanding and consideration of tribal worldviews about wolves. Tribal worldviews of wolves are misconstrued as 'cultural benefits' tribes receive from the existence of a wolf population, when in fact tribal worldviews consider *each individual wolf* as a *person* and *relative*. Cultural respect and sensitivity towards such views, shared by many non-tribal members, demand the strict mitigation of lethal measures, especially recreational killing, as opposed to their current promotion in the plan.
- In general, all omissions of scientific literature, the arbitrary prioritization of policy objectives, the rhetoric of the plan and the dismissal of public values and concerns *for wolves* point towards a biased, unscientific and instrumental view of wolves that promotes values contrary to broad public perspectives on wolves.
- 'SOM' wolf estimation methodology – From a recent critique: "The new methods sacrifice precision, but are believed to retain adequate accuracy and sensitivity to changing conditions for reliable decision-making. We review evidence for the accuracy, precision, and sensitivity of the new 'scaled occupancy model' (SOM) applied in Wisconsin. We conclude that the Wisconsin method would systematically overestimate wolf abundance by large (but currently incalculable) margins. Because Wisconsin, similar to other states, not only changed to unverified methods but also implemented widespread wolf killing, shortcomings in their estimates of wolf abundance may have far-reaching consequences for population viability and confidence in state wildlife managers. We discuss findings from Wisconsin alongside similar findings for other states' occupancy models being insensitive to human causes of mortality that have recently increased. Overall, Wisconsin's proposed method for estimating wolf abundance shows significant departures from best practices in scientific measurement. Verification will require independent replication and unbiased tests at multiple scales in multiple habitats under different human-induced mortality rates, and peer review before the new methods are considered reliable." (Treves & Santiago-Ávila, 2023)

Re: My Professional Comments and Recommendations on the Draft Wisconsin Wolf Management Plan 2022

Thank you for the opportunity to review and provide comments on the *Wisconsin Wolf Management Plan* (dated 9 November 2022). I provide overall comments in the body of this letter and more specific, line-by-line comments on the draft of the plan as an attachment to this letter. These comments represent my personal opinion and do not necessarily reflect the opinions of my employers, clients, or organizations that I am a member of.

Throughout my career I have served as a Wildlife Ecologist/Biologist with State and Federal Agencies and with a natural resources consulting firm (https://www.northern-ecologic.com/team.php). I am a Certified Wildlife Biologist® and elected Fellow of The Wildlife Society and am an active member of The Wildlife Society at State, Section, and International levels. I am a member of Wisconsin's Green Fire Wildlife Work Group and an elected county delegate of the Wisconsin Conservation Congress.

I commend the Department of Natural Resources for drafting a comprehensive plan for ensuring sustainable management of the gray wolf population in the State. My comments and suggested edits on this plan are intended to give the Department insights to potentially revising and improving this document and the over-all management program for gray wolves in the State.

General Comments

Executive Summary

- Executive summaries should restate the purpose of the plan, highlight the major points of the plan, and describe any results, conclusions, or recommendations from the plan. This one does not get beyond the purpose of the plan while ignoring the rest.

Section 1: Gray Wolf Biology, Ecology and Population Dynamics

- This section should be revised to better present and interpret the significance of the information presented here to actually managing the gray wolf population in Wisconsin and to the development of a management plan for gray wolves in Wisconsin. This section should help describe the biological basis for the approaches in this plan for managing gray wolves with references back to this section that support the Objectives, Strategies, and Products. As it is currently written, it has little direct connection to the management philosophy and direction that you establish in the plan. As a result, it is really not of much value to this document.

- The status of gray wolves is described in the contiguous United State and immediate adjacent areas in Canada, but not in Alaska. Since you cite studies completed in Alaska in the document, you should include Alaska in that discussion.

- Many places in this document English units of measurement are used without reference to metric units. In other places, both are presented with metric units being the primary. One, or the other, should be used consistently (I recommend presenting both units of measurement).

- Selective Predation and Chronic Wasting Disease – The science behind gray wolves affecting the spread of CWD is not conclusive but it seems as if you are passing off on the concept too quickly. This discussion is hardly an extensive assessment of the strength of the science supporting it. Once that is done, it may be reasonable to accept it as a hypothesis, with caveats, and incorporate the concept into development of management strategies. Wisconsin may have the best opportunity so far to examine this with healthy populations of gray wolves and deer co-occurring with CWD actively spreading in the deer population.

- Prey Regulates Wolf Populations – Despite the statement "*To date, prey abundance does not appear to be a limiting factor for wolves in Wisconsin*", this section is presented in a manner that fully supports the hypothesis that "*prey regulates wolf populations*". This ignores the literature that supports the hypothesis that food may set an upper limit, but before this limit is reached, other factors, particularly higher mortality due to intraspecific strife, reduce population density (e.g., Smith et al. 2020).

Section 2: Human Dimensions and Cultural Significance

- The Department is to be commended for its effort to learn about citizen's attitudes concerning gray wolves in Wisconsin. I had experience with social science surveys addressing wildlife issues while with the New York State Bureau of Wildlife. The 59% response the 2014Wisconsin survey received was very high for this type of survey. Therefore, these data can be considered robust. The lower 38% response rate in the 2022 survey is still a good response and can also be considered robust. This response is reflective of people's changing general response to opinion surveys. This whole body of research is notable because it describes changes in attitudes from 2014 to 2022. This provides a really good opportunity to explore and understand people's changing attitudes about gray wolves in Wisconsin.

Section 4: Wolf Management in Wisconsin: From Recovery to Sustainable Management

Wolf Management Plan Goal

"*The preceding sections of this management plan endeavor to provide a foundation of science-based information on wolves in Wisconsin and define the current biological and social context in which wolf management must occur*."

- That may have been the intent but I do not think this was accomplished. A lot of information was presented but this would have been much more meaningful if it had been presented in the context of how that information was used to develop the management plan.

"*…while explicitly recognizing that inherent tradeoffs exist among some of the objectives*."

- It is certainly good to recognize that there will be trade-offs associated with the management strategies that form the basis of this plan, but how

those trade-offs are addressed and resolved is critical. Does this plan do that?

Goal Statement

- A goal is an outcome that is desired to be achieved. So, "Objective A" is an outcome and would be considered a goal. "Objective B" can be considered an actual objective which, when met, would help to achieve the stated goal. However, an objective is a specific and measurable action that can be reached in a short amount of time and has the following attributes: specific, measurable, achievable, relevant, and time-bound. I recommend the goal, objective, and strategy framework be rewritten to better fit traditional structure. Otherwise, this could lead to misunderstandings and confusion.

Implementation of Wolf Management Plan Goal

"*To effectively implement the plan goal, the use of a formal yet adaptable approach to evaluating objectives and guiding decision-making is recommended. This process should be values-based, informed by science, and include routine evaluation aimed at measuring progress towards management plan objectives. This plan recommends engaging the department's Wolf Advisory Committee in the process to annually assist in reviewing data, metrics and trends related to existing conditions on the ground in each wolf management zone.*"

- This is why there should be 2 committees, a Science Committee that will be involved in this aspect of the plan process and a Stakeholder Committee to ensure that the plan's implementation addresses society values. Enlisting the assistance of knowledgeable scientists to review data, metrics, and trends will result in better science applications; involving stakeholders in these reviews will not result in the best science. Having a mix of stakeholders involved in this aspect would result unhelpful discussions and watered-down "science".

"*Table 13. Wisconsin wolf management plan objectives and associated metrics by which to evaluate progress towards those objectives. Metrics may be qualitative or quantitative. Metrics may also be refined or modified in the future as experience is developed, including the addition or subtraction of metrics.*"

- The metrics are one of the most important components of the management plan in determining how well it is being implemented and how well implementing the plan is resulting in sustaining the gray wolf population in the State. However, this component appears to be one of the least well-

developed aspects of the plan. It is questionable whether the metrics listed are the most appropriate, the basis of many of the metrics is not clear, how the state variables of the metrics will be determined is not explained, and how the information gathered for each metric will be evaluated is not presented. The metrics should be the basis of a comprehensive monitoring plan that accompanies the management plan. The management plan should not be implemented until a monitoring plan is completed and ready to be applied.

A metric is a standard by which results can be measured. It is not clear to me how "qualitative" metrics can be meaningfully measured and evaluated.

Wolf Management Zone Definitions

"*This approach also reflects results of the 2022 public attitudes survey which found the most common preference regarding wolf distribution was for wolves to occupy about the same amount of the state as their current geographic distribution*"

- This is really good. You use the results of the public survey to directly develop an aspect of the plan. The information presented in Section 1 and Section 2 should also be directly applied to the development of the plan in Section 4. Otherwise it is not clear why Sections 1 and 2 were included in this document.

Zones 3 and 4

"*The plan recommends that the leading objectives within these zones be twofold: addressing and reducing wolf-related conflicts (Objective B) and providing multiple benefits associated with the wolf population (Objective C).*"

- This approach suggests the Department's primary method of reducing wolf-related conflicts is increasing harvest of wolves until a number of packs are eliminated. Findings in the published literature indicate that research results were unable to support a hypothesis that public harvest of wolves is a primary factor influencing decreases in wolf-related conflicts (e.g. ,DeCesare et al. 2018, Kareiva et al. 2022). However, to be most effective, lethal control should target definitely known individuals responsible for livestock losses (Bruns et al. 2020). Non-lethal deterrents are generally more effective for reducing wolf-related conflicts.

"*Ensuring a healthy and sustainable wolf population to fulfill its ecological role (Objective A) is also recommended to be considered in these zones, but decision-making primarily be guided by the leading objectives (B and C).*"

- This is a bit confusing. Is the Department suggesting that they will not necessarily manage for a healthy and sustainable wolf population in these zones? How can "multiple benefits" be assured if the population is not sustainable? Will the Department prescribe harvest levels that will result in the eradication of some wolf packs in these areas?

Objective A: Ensure a Healthy and Sustainable Wolf Population to Fulfill its Ecological Role

- It would be helpful if this section on defining objectives were moved to just after Table 13. That way the information provided here would be available to the readers when they read when and where these objectives would be implemented.

- Are **benchmarks** different than metrics? Listing these "benchmarks" here is not very useful without discussion of how and when these benchmarks will be measured, what the benchmark value is that, when reached, or when not reached, will require action, and what that action would be.

Product A1b: Ensure the late-winter wolf population abundance is responsibly maintained above **federal and state listing thresholds**.

- Really? These thresholds were based on antiquated data and not a full understanding of the ecological relationships in this area. These numbers should not be carried forward in this plan. This product should be deleted.

Product A1d: Continue annual **winter snow tracking surveys** to collect data on the midwinter wolf population.

- It should be recognized that with the advent of global climate change snow cover adequate to perform these surveys will decline throughout the range of gray wolves in Wisconsin. There should be a strategy in place to guide adaptation to this change.

Product A4a: Work with department wildlife health staff to assess current and emerging threats to wolf population health.

"…*emerging threats, such as* ***the potential impacts of climate change*** *on wolves, their prey, and their habitats, must be considered and require a nimble approach to respond appropriately*."

- This needs to be elevated to Strategy level and not buried in the population health section. An adaptation strategy for how to address the effects of climate change on the wolf population needs to be developed and implemented as part of this plan. Climate change is going to affect all aspects of this management plan and needs to be addressed **now**.

Product C1a: Utilize public harvest to help manage wolf populations consistent with zone-specific objectives.

"*Once such zone-specific population objectives are identified*…"

- How specific are these objectives going to be? Just decrease, increase, or maintain the wolf population will not be specific enough to inform decision making (e.g., what are the confidence levels on the results of the scientific population modeling?). Further, zones will be too large to address local issues (e.g., depredation). As discussed previously, harvest objectives will not likely result in addressing depredation issues. Those issues will need to be addressed individually, on a site-by-site basis.

Product D1c: Ensure the 2022 Wisconsin Wolf Management Plan is widely available to the public.

"…*this plan serves as an effective outreach tool to increase public understanding of wolves and help citizens make informed decisions regarding wolf management*."

- Only the most dedicated people with a well-developed interest in wolves will access and read this plan. The plan is not in a form that will serve as an effective outreach tool. The format of the plan is not inviting to the public and it should not be relied on to provide information to the public.

Literature Cited

- The format of the citations in the text is not consistently the same throughout the document (e.g., placement of commas in the citations).

- I noted that several (many?) citations in the text (e.g., Paquet and Carbyn 2003) are not included in the Literature Cited section. All citations in the text should be checked to ensure that they are fully described in Literature Cited.

- The format of the references listed in the Literature Cited section is not consistent.

- It would be helpful if you included the DOI (Digital Object Identifier) for each of your references in the Literature Cited section. A DOI will help readers of this document to easily locate a cited publication from your reference.

Additional Comments

- Historical funding of the wolf program as presented (pages 62-63) is useful information, but implementation of the tasks listed in this plan will require a substantial increase in funds above current expenditures. A complete evaluation of this plan is not possible without presenting a proposed budget for future gray wolf management and research. This information is necessary to gain approval of the plan from stakeholders, leadership in the Department, and the Legislature. It would also be helpful in effort to secure funding to implement the plan from cooperators, collaborators, and, potentially, granting organizations.

- A plan like this is not complete without a thorough discussion and presentation of a monitoring strategy. Additional effort is needed to fully describe the metrics (i.e., a system or standard of measurement) and the benchmarks (i.e., a standard or point of reference against which things may be compared or assessed) presented in this plan. What, exactly, will be measured or established for each, how will the measurements and assessments be accomplished, and what will be the points for the metrics and benchmarks where a change requires a response? Without knowing these aspects it is not fully possible to assess how the plan will be implemented or, perhaps, even be successful.

- This plan uses many technical terms to present and describe the biological and cultural background and strategies that make up this proposed effort to manage gray wolves in Wisconsin. A glossary of these terms is needed to ensure all stakeholders fully understand what is being proposed and to ensure that all language is interpreted in the correct context.

I have also provided more specific, line-by-line, comments in the copy of the *Wisconsin Wolf Management Plan* included with this letter. Although I made comments and suggested edits throughout the text, I specifically concentrated on the Introduction, Section 1: Gray Wolf Biology, Ecology and Population Dynamics, and Section 4: Wolf Management in Wisconsin: From Recovery to Sustainable Management.

Wisconsin Wolf Management Plan

2022

A plan for stewardship, conservation, and management of the gray wolf in Wisconsin

Wisconsin Department of Natural Resources
Bureau of Wildlife Management

DRAFT

Comments from LH Suring - 303 individual comments noted in a copy of the draft plan

WOLF MANAGEMENT PLAN COMMENTS

SUBMITTED BY: AL LOBNER

I have a significant amount of concern regarding the proposed Wolf Management Plan. First off there were several instances where the surveys used were from year 2014. In most instances we would be in the initial stages of developing a new plan and those surveys would no longer be relevant.

Another concern is statements made by individuals were contradictory to the graphs and surveys that they used to make their points. There were comments made that instances of aggression were more prevalent in bears that it was in wolves. Although that may be the case, I would like to see these numbers in relationship to the population of their respective species. I believe this would tell a different story,

There was also a comment that in the plan that the native people of the region were considered predators to the wolves, coyotes, fox, raccoon, cougars and bobcats. This does not coincide with what is being said from the natives today. Today they say the wolf is their brother. Which is the truth?

The comments in the plan regarding the relationship of range expansion vs population growth were also quite interesting. According to David Mech in his book, Wolves: Behavior, Ecology, and Conservation written in conjunction with Luigi Boitani, explains why packs get smaller when the landscape gets saturated with wolves. They will move to places that are not optimum because it is the only place, they can live without being killed by other packs in the region.

Over the years I have heard from pro-wolf groups that the wolf is considered part of the Public Trust Doctrine. I have read extensively on this subject and although there are groups that feel other things should be included in this Doctrine none have of them have succeeded in this effort. Only the high water to low water including (high tide to low tide) is the only premise that has met the juris prudence requirements of the Public Trust Doctrine. The comments in the wolf plan should not have included wolves and the Public Trust Doctrine together in my opinion. Just because someone says it doesn't necessarily make it true.

Future DNR Wolf Advisory Committee participation members was also a quite disturbing to me. There were several pro-wolf groups included in this committee and only one sportsman group (Wisconsin Trappers Association) included in the future committee.

Last but not least I strongly disagree with the buffer zones around the reservations. As taxpayers we have all contributed to have National Forests, State Forests, County Forests, and personal property managed. I don't feel it is right to have these public and private lands controlled solely by the tribes when everyone has contributed to keep these properties managed for future generations.

Re: Wolf Mgmt

FOR your information

3 years ago we had coyotes on our roads + fields.

Homes + condos built pushed out or eliminated them.

Now I have tons of rabbits + rodents to eat my garden + I need to fence ~~every~~ over everything

We meddle too much with nature.

I am very very very against these TRAPS.

This is extremely cruel!

Do not do this, to the wolves!

How many wolves there should be, I don't know. Transport them somewhere else!

P.S. I have always had a Dog with no problem with coyotes -

WI Draft WMP Talking Points

What we like:

We appreciate the efforts of all WDNR staff involved in updating the state's wolf management plan. Although we believe the current plan needs significant updating (see next section), we recognize the efforts and improvements made to the previous plan, including:

- Wolves in WI will no longer be managed by reference to the old numerical goal of 350 wolves.
- There is much greater recognition of the ecological role of wolves
- The inclusion of a social survey, which notes increased positive views of wolves, knowledge of their ecological roles and increased opposition to the motives and methods for killing wolves
- The adoption of proposed buffer zones around tribal reservations (i.e., previously no buffer zones existed)

What we don't like:

- The current draft does not reflect the best available science, and is missing a substantial amount of scientific literature on (see reference list below):
    - wolf ethology, sentience, sapience, sociability, agency and wellbeing
    - effectiveness of non-lethal interventions, especially relative to lethal ones
    - the impact of widespread killing on wolves' physiology, behavior, wellbeing, social dynamics, ecological relationships and evolution
- The above scientific omissions, combined with the emphasis on and promotion of sustainable recreational killing and consumptive users as a main management strategy, results in a biased plan that runs contrary to scientific evidence despite much of this omitted scientific evidence being more recent, numerous and of stronger inference.
- The plan should strictly curtail any lethal management of wolves except in extremely rare circumstances of immediate defense of life.
    - A substantial body of research documenting human-caused mortality in North American wolves, including Wisconsin wolves, has found that policies allowing liberalized killing of wolves result in a direct increase in the hazard and incidence of illegal killings.

    - Hounding or hound training, which are akin to allowing legalized dogfighting, should be illegal or severely restricted as this practice is extremely cruel to wolves and hounds alike and is not supported by the majority of hunters or the broad public.
- The plan should prioritize wolf protections and concentrate solely on non-lethal management of wolves in response to livestock conflicts to ensure ethical coexistence.
    - Despite Act 169, which mandates a wolf hunting season, the department can still restrict the implementation of lethal methods by setting minimal quotas, including a quota of '0' wolves, restricting timing and methods.
    - Several studies have proven a proactive non-lethal approach leads to better conflict mitigation.
    - Lethal management often fails to provide a long-term solution to wolf predation and has the least consistent success rates when compared to non-lethal practices. In addition, there is significant evidence showing that lethal wolf management may be less functionally effective at mitigating subsequent livestock losses than non-lethal deterrents.
- The plan should *require* the implementation of abatement measures as well as the use of non-lethal conflict minimization techniques by domestic animal owners for the latter to receive compensation for confirmed predation.
- The plan also runs contrary to public values towards wolves (and omits mention of such majority values from the plan), despite department surveys evidencing that the broad public cares about wolves as individuals (and not just for the viability of the population). Given the recent liberalization of killing wolves by the state, it would be incredibly informative to note majority support of the following reasons for opposing a regulated wolf hunting/trapping season (which are all omitted from the plan): opposition to specific methods of harvest like hounds (64%) or traps (70%), feelings that hunting wolves is unnecessary (62%) or culturally offensive to Native American tribes (57%).
    - All such reasons convey majority disagreement with practices currently promoted and endorsed by the legislature and the WDNR, and such a conflict between managers and the public should not only be acknowledged, but foregrounded and carefully considered in policy (instead of dismissed).
    - Such decisions to omit literature or downplay evidence (e.g., such as majority opposition to killing wolves and their reasons) are contrary to principles of scientific integrity (e.g., present all relevant scientific evidence to the public) as well as ethics (e.g., disguising ethical decisions, such as recreational wolf killing, as robustly supported by science).
- Conflicting agency objectives (e.g., optimizing public hunting and conflict mitigation) are not only not acknowledged, but even misunderstood as harmonious, against the body of scientific evidence. That culminates in the prioritization of consumptive values and policies; e.g., according to the body of scientific literature, use of lethal methods, and

especially public hunts, are contrary to most objectives relevant to: harm mitigation, the wellbeing of wolves, their ecological roles, and their non-exploitative enjoyment (i.e., Objectives A, B, D and F).

- There is a stark lack of consideration for individual wolves, wolf population health (including wellbeing), and measurable indicators for assessing any harms barring disease prevalence (e.g., accounting for cortisol levels or other stress hormones, measures of pair/pack persistence)
- There is an inappropriate understanding and consideration of tribal worldviews about wolves. Tribal worldviews of wolves are misconstrued as 'cultural benefits' tribes receive from the existence of a wolf population, when in fact tribal worldviews consider *each individual wolf* as a *person* and *relative*. Cultural respect and sensitivity towards such views, shared by many non-tribal members, demand the strict mitigation of lethal measures, especially recreational killing, as opposed to their current promotion in the plan.
- In general, all omissions of scientific literature, the arbitrary prioritization of policy objectives, the rhetoric of the plan and the dismissal of public values and concerns *for wolves* point towards a biased, unscientific and instrumental view of wolves that promotes values contrary to broad public perspectives on wolves.
- 'SOM' wolf estimation methodology – From a recent critique: "The new methods sacrifice precision, but are believed to retain adequate accuracy and sensitivity to changing conditions for reliable decision-making. We review evidence for the accuracy, precision, and sensitivity of the new 'scaled occupancy model' (SOM) applied in Wisconsin. We conclude that the Wisconsin method would systematically overestimate wolf abundance by large (but currently incalculable) margins. Because Wisconsin, similar to other states, not only changed to unverified methods but also implemented widespread wolf killing, shortcomings in their estimates of wolf abundance may have far-reaching consequences for population viability and confidence in state wildlife managers. We discuss findings from Wisconsin alongside similar findings for other states' occupancy models being insensitive to human causes of mortality that have recently increased. Overall, Wisconsin's proposed method for estimating wolf abundance shows significant departures from best practices in scientific measurement. Verification will require independent replication and unbiased tests at multiple scales in multiple habitats under different human-induced mortality rates, and peer review before the new methods are considered reliable." (Treves & Santiago-Ávila, 2023)

Rating: 4-5

TO: Randy Johnson

FROM: Keith McCaffery – Deer person

SUBJECT: Wolf Mgt Plan comments

Overall, I'm quite enthusiastic about the plan, but I have just a few comments. One of my major concerns is using the absence of quantitative goals for deer as a justification for not having quantitative goals for wolves. We had a 60-yr history of unit-specific deer density goals based on forestland KCC and farmland herd manageability that was dumped by the Walker Admin. Proper deer management calls for restoring these and I don't want to see the absence of quantitative goals for bear and wolves to be used against reinstating deer density goals.

Pp.17, 105-107: I subscribe, hopefully, to the hypothesis that wolf predation may be deterring CWD transmission (e.g., Shell Lake, Camp 10, near Three Lakes pen). We may have new tests in Adams and Langlade counties.

P.97: One of the goals should be to draw attention to the strictures of Act 169. It bothers me that DNR tends to consider statutes as concrete. Same goes for legislative restrictions of deer harvest strategies.

Pp. 103, 158: WGF strongly recommends adding western Langlade County to Zone 2. I've wondered why the area (west of this Langlade change) all the way to Hwy 73 should not be part of Zone 1. I'm looking mainly at the contiguous habitat including the Mondeaux District.

P.123: Instinctively, I react badly to qualitative quotas of more-same-fewer. My brother says that this is the way squirrels count. My deer background affects mv reaction!

P.159-165: WGF recommends adding area in square miles for each zone. I would suggest that you show (also) area of suitable wolf habitat based on our best understanding at this time.

1/17/23

Wolf Managemant Plan:

The final draft should make sure that the wolf population does not decrease in numbers.

Hunting and trapping are the most harmful activities causing the wolf population to go down.

In the draft, there should be a provision that hunters and trappers be heavily fined when not following the rules. It was totally shocking when the wolf kill exceeded the quota by 83%. In some cases, where hunters and trappers show that they don't care and repeat violations, their licenses should be revoked.

Thank you for allowing me to express my thoughts on this matter.

Sincerely,
Ruth M. McCloud

Dear Wolf Management Committee,

My name is Chris Meinert. I am 50 years old, married to Sara Meinert. We have 3 children who are 19, 17, and 9 years old. As a family, we have been living in Wisconsin our whole lives. We also all started hunting at the age of 12 or before. My parents and I have a cabin in Iron County. We have been bear and deer hunting in this county for years. We quit deer hunting in Iron county about 10 years ago because of how drastic the deer population has decreased because of wolves. We now can only really find a good amount of deer near homes or towns where wolves are not. We used to see deer all over and had to avoid them on the roads. I feel bad for the few deer that make it without getting hit on the roads because they can only live near populated areas without wolves eating them. We still bear hunt in Iron County. We used to have three areas to hunt since I was a kid. Now we have had to leave an area, 3 years ago, because the wolves killed our dogs. A few years ago they killed our two lead dogs. These dogs were my daughters' babies and it was devastating seeing them, knowing their dog was gone. Two of my daughters started to not even come up north anymore because they were scared the wolves were gonna kill their other dogs and they did not wanna see it. There are other hunters that also have this problem, not just in our county. It seems that as soon as the wolves hear the dogs they start to try and hunt them. This past year we lost another area because a wolf pack moved in there. Now we are down to just one area to hunt which makes it very hard to get to the bears while keeping our dogs safe. My family and I have started hunting other states in the south because they do not have to worry about wolves. It is very hard to train young dogs when we are scared to turn them loose because if they fall behind or go the wrong way, wolves will most likely get them. I know there are other groups starting to look at other states to hunt for the same reasons. I do not want to have to move but I love my dogs and they wanna hunt so we have to fulfill their needs without having wolves to worry about. The establishments up in the north woods thrive on tourism and hunters. I know they are hurting business because there is very little big game in northern Wisconsin. Wisconsin wanted to sustain a population of 350 wolves. The estimated population is now over 1,200 wolves. Anyone that spends time in the wilderness doesn’t believe that number is accurate. My question is, why with the wolf population at over 1,200 are we not doing anything about it if the goal is 350 wolves? This doesn’t seem hard for me to figure out! Does anyone realize that deer have 1-2 fawns a year. Bears have 1-2 and occasionally 3-4 every other year. While wolves are from the dog family so they can come in heat every 6 months and have up to 8 pups each time. I think wolves are an awesome animal but not for the state of Wisconsin. I wish as a state we could do something about maintaining the 350 wolf population. We have seen the money spent to reintroduce the wolves using our hunting license and atv registrations that we feel could go to a much better use. My family/friends and I believe that we should have an open season until the number gets to 350 or less. Not only is it a concern to us hunters, but also the animals in the environment that are trying to survive while being hunted, especially pets. Thank you for your time, I really think that you guys can make a change for the better before the tourism and hunters never go back up there and the north woods fall apart.

ASSESSMENT OF WISCONSIN WOLF MANAGEMENT PLAN

To Whom it may concern,

I have held a Wisconsin bowhunting license for 57 years and hope that my dedication and years of experience give weight to the opinions I am about to share about Wisconsin's Wolf Management Plan and wolves in general. I spent a great deal of time over several days reading the plan and taking notes in order to make an educated assessment of it. I hope what I am writing is read and not just filed or discarded. In case you don't get past the first page, I am posting my basic message here and will also repeat it at the end.

We have too many wolves the State needs to seek to manage their numbers as close to the 350-animal social carrying capacity number which was originally "sold to" sportsmen as the plan!

The following are my comments and opinions regarding items as referenced by page number from the plan.

Page19, Impacts of Human-mortality

Several studies were cited and summarized as follows; "*current research suggests as much as 24-29% of a wolf population can be removed via human-sourced mortality before populations begin to decline*". **By the State's own conservative estimates, we have over 1,100 wolves minimum which means up to 319 could be harvested annually before the overall population would go into decline**.

Page 20, Impacts of Regulated Harvests on Wolf Dynamics

A 26-year study of collared wolves in Alaska (Borg et al. 2015) revealed that "*breeder mortality and pack dissolution had no significant effects on either immediate or longer-term population dynamics in their study area, indicating that strong compensatory mechanisms may be able to reduce the negative impacts of breeder loss at the population level scale*". **This indicates that the argument of loss of the alpha male or female and possible dissolution of packs should not be considered as reason to prohibit hunting and trapping**.

Page 36, 2022 Wolf Attitudes Study (item5)

Wolf hunting has the support of 46% of the public to 29% opposed. **Hunting and trapping should be scheduled yearly once the federal protection is removed**.

Page 38, Wisconsin's Tribal Perspectives and Cultural Significance

The State of Wisconsin asked for a written narrative on the cultural significance of wolves from the eleven tribes within the State as well as the Great Lakes Indian Fish and Wildlife Commission. Only the Commission and 3 of the eleven tribes responded. **With all due respect to the tribes and their rights under the treaties signed by their ancestors, I don't think that with only 27% of the tribes responding we should be held hostage to not having a wolf season. In addition, since they claim the wolf is their sacred brother who they will not kill, when a season is again instituted and a quota set there should not be 50% allocated to the tribes unless the desired harvest number is automatically doubled to**

compensate for that. Otherwise, the wolf population will continue to explode until it reaches the biological carrying capacity which will be a continuing source of ire to deer hunters. We don't allow deer to reach the habitat's carrying capacity nor should we let the wolves.

Page 46, Gray Wolves in Wisconsin

The State has maintained that the re-introduction of wolves happened naturally. **The last paragraph on page 46, however, reveals that the State did in fact assist in their expansion by relocating problem wolves to other counties within the State**.

Pages 47 & 48, Wolf Population Depictions by the Decades

The depictions show that Wisconsin's wolf population grew from an estimate of 25 in 1980 to 1034 in 2020. Of particular note is the fact that in the span from 2010 to 2015 the population increased 6% while sustaining hunting losses during three consecutive years. By DNR accounting it went from 704 to 746. Interestingly that 746 is the same number of animals harvested by hunters during those three seasons (from page 52 of the report). **This should give rise to a conclusion that either wolves are reproducing at an amazing rate, or the population estimate is far below reality.**

Page 50, Wisconsin Grey Wolf Population from 2000-2021

For the year 2020 the chart lists two sets of numbers for both pack numbers and total population. The population change went from 1,034 to 1195, an increase of 161 animals while the pack count went from 256 to 316, an increase of 60. It has been the DNR's claim that packs average 4 in number. With the new estimate of 60 additional packs at 4 per pack the increase in overall population should have been plus 240 animals not the 161 listed which would push the population total to 1,274 not 1,195. **For those of us who pay attention to detail this only adds to the suspicion we are being deceived by the department**.

Page 52, Mortality of Wolves in Wisconsin

Studies referenced on this page mention that mortality caused by hunting is partially offset by a reduction in natural mortality, in other words compensatory. The DNR justifies higher antlerless deer quotas to offset what would otherwise be compensatory losses. **This adds support to having a sustained harvest of wolves in the State.**

Page 54, Biological Carrying Capacity

The 2015 IBSE model referenced on this page (Stenglein et al.2015) predicted the "*Wisconsin wolf population, without harvest, stabilize around 1,242 wolves (SD) after 50 years*". From page 50 of this report there were estimated to be 746 wolves in 2015 and as I mentioned 2 paragraphs back was already probably 1,274 by 2020. **So according to the study the wolves have reached their biological carrying capacity in only 5 years, 1/10th of the time it was estimated to take. Once again it shows the need to hold regular hunting and trapping seasons to control the population**.

Pages 62 & 63, Wisconsin Gray Wolf Expenditures

Wisconsin reached the original goal of 350 wolves by 2004 when the Stated estimate was 373. In that year the State's wolf program costs were $195,646 of which $76,867 was depredation compensation payments. By 2020 the estimated population has risen to 1,242 with yearly costs to the State reaching $315,266 and depredation compensation $242,528. That means that we spent $522 per wolf in 2004 compared to $253 per wolf today. That is an improvement, but I can't help but think of the uproar if the State had to spend an equivalent amount of money to maintain the deer herd. If the herd is 1.5 million, that cost would be $380,000,000. In 2020 the State paid out $760,000 for deer damage. That is $2 per deer, which is .8% of what costs were per wolf. **The short of it is the State is spending too much money for merely the frivolity of having wolves on the landscape and not incorporating a hunting season with it. I say this while pointing out the hypocrisy of promoting the presence of wolves on the landscape of the north to try and appease the wolf-favoring population in the south who would not tolerate them in their urban setting.**

Page 125, Product C2c Zone Specific Harvest Tags

The proposal to go to zone specific harvest tags to reduce the possibility of overharvest in an individual zone is an unnecessary step which will exacerbate an already unfair system which gives the advantage to trappers and hound hunters over those using predator calls. I speak from experience having drawn a harvest tag in 2013 intending to hunt zone 1 only to have it close in three days leaving me no alternative but to go to another zone to even have a chance. A better change would be to allocate method specific tags.

We are never going to know what the sustainable wolf harvest is until we have regular seasons which are based on the rise or fall of animals taken from year to year. That system has worked for deer management. With that said, if over 600,000 deer hunters across all the seasons spanning 4 months, only harvest approximately 25% of the 1.5 million deer in the State, how can anyone realistically think hunters took out 25% of the wolf population in 2 days during the 2022 hunt? Either wolves are the dumbest animal on four legs or there are far more wolves than we are led to believe.

CLOSING STATEMENT

It would seem that money is no object with the DNR when it comes to wolf management so as an avid hunter I would like to see the State actively pursuing the de-listing of wolves in the courts as opposed to waiting for the federal government to move on it. Once de-listing happens, schedule hunting and trapping seasons with a balanced allocation of harvest tags made available to accommodate callers, trappers and hound hunters. Set the harvest goal at 29% of the estimated fall population yearly until the over-winter population estimate nears 350 animals which was the social carrying capacity number sold to the public when the wolf re-introduction got started.

1/23/2023

ALCIVIA

D.N.R.

I hope you start using facts and listen to the people who live in the areas affected by wolves to cut down there numbers.

I've hunted in Wisconsin for over Sixty years and have a cabin in Vilas Co. It used to be great deer hunting I quit going up north the deer numbers are down to nothing. There were a lot more coyotes and bobcats up there then and the same number of bears as now so don't pin it onto them.

All of Central Wisconsin except around open farm country is seeing the same effects of lower deer numbers and it will only get worse.

You are loosing Wisconsin greatest Sport and Resources Don't put antis and politics above common sense.

Set the Wolves population goal to 350 wich Eighty Percent of the People affected want.

Lynn Moeller

Wolf Management Plan Comments
Why 350 made sense

Between 2002 an 2003 the estimated over winter wolf population exceeded the 1999 plan of 350. The number was developed through careful deliberation considering the wolf's impact on environment, social interactions, and sustaining a wolf population within the state. Sustaining a wolf population according to the USFWS Endangered Species Act requires the wolf population reach and hold a population of 100 animals for five years. There is sufficient evidence that the population of 350 is spot on and that the number exceeding that is creating intolerable conditions within the state. By looking at the impact the wolf has had on the state once 350 was approached and then exceeded it is clear that the state has been forced into a downward spiral that no longer has an upside. Ignoring the impact the wolf has had or attempting to minimize the impact through distractions such as there are plenty of deer in the state; or livestock depredation is isolated to a few farms; or forest improvements are simply painting over the problems with rose colored glasses.

As stated in the WOLF ADVISORY COMMITTEE MEETING 9/10/2014 "There was an agreement between the DNR and sportsman in the 1980s to help fund the restoration of wolves in the state; sportsman provided $1 million and were promised that 80 wolves would be sustainable."

Between 1980 and 1995 the number of wolves was revised to 100, and in 1995 after careful consideration of scientific, environmental and social impacts, Federal and State regulations and goals, along with carrying capacities was set at 350. This was revised in 1999 to a plus or minus 10% of 350 as the overwinter goal as more reasonable to maintain. That 1999 plan remains in place as the 2022 Plan is under consideration.

Since the wolf population eclipsed the 1999 plan we have considerable data to consider if a revision from that plan is warranted. We have personal experiences, testimonies, depredation claims, deer harvest records, and elk reintroduction population tallies before and after up to the current estimated overwinter population of 1,034-1,057 in 2022.

There has been extensive work and analysis to determine the wolf's tendencies, needs, and abilities to survive by L. David Mech, Dr. David Mladenoff, Sarah Pratt, Dr. James C. Kroll, Adrian P. Weydeven, Teb B.Lyon & Will N Graves, and Paul Swanland who I rely upon considerably to understand wolf dispersal, colonizing, and optimal survival conditions.

Initial studies led to the conclusion that wolves need prime territory, avoidance of roads, and people. More recent studies support a wider area of Wisconsin suitable for wolf distribution based substantially upon prey availability – deer, elk, and beaver (one study included turkeys) as well as avoidance to people and roads. It is these revised studies that support the 2022 plan without a prescribed population. My personal theory is the availability of prey is the only limiting factor to wolf distribution. Being an apex predator puts them in the highest category to adapt to a complex mix of environments as we are seeing their dispersal support that conclusion. "Wolves present such challenges because they adapt to many human land uses (Blanco et al. 1992, Fuller et al. 1992, Thiel et al. 1998)."

My first consideration why the 1995 & 1999 plans are well thought out population goals regards the impact of wolves on deer and elk. Elk were introduced in 1995, areas already habituated by wolves. As the wolf population grew to and eclipsed the 350 one of the first casualties was elk recruitment. Recruitment of elk was zero for many years. When I addressed this with WDNR personnel I was informed it was primarily bear and coyotes. I rejected this opinion as they existed prior to wolves and recruitment was never zero. Not until a bull elk was killed by wolves along with Kentucky concerned about providing more elk did the WDNR consider lethal action required to support the elk introduction.

When I look at the deer harvest in wolf territories, we see a similar correlation. Beginning in 2003 as wolf numbers climbed, deer harvest declined and has steadily diminished. Hunters who hunted the north have reported seeing wolves and no deer. In Vilas County I hunted there since I was 16 years of age. My father and I would count shots in the fist hour. Our count was usually around 35. This last season I counted 3 shots for the four days I hunted. In the presence of wolves all CDAC's voted for growth in deer herds. When I bring this subject up to WDNR personnel I was told I am not considering bad winters and winter kill. I consider it however scouting in April in the area we hunt found a deer yard where the evidence of over 40 deer could be counted killed and completely consumed. We simply no longer see deer tracks, but plenty of wolf tracks. Yes this is anecdotal evidence.

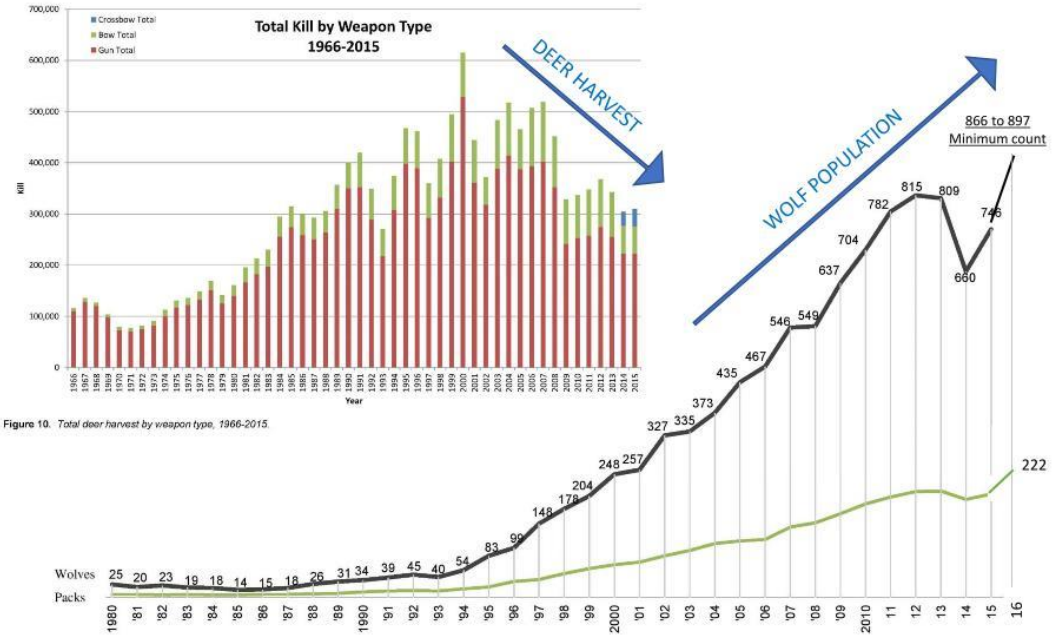

Figure 10. *Total deer harvest by weapon type, 1966-2015.*

Figure 3. Changes in Wisconsin Gray Wolf Population: 1980- 2016

Many see wolves as a method to reduce deer costs. This argument reminds me of the same argument why we should allow recreational pot because alcohol is worse. So we compound the problem by having two expenses on the books rather than one and even if marginally successful and the deer herd is drastically reduced the 600,000 hunters no longer participate.

As compiled by Welcome To Hunting Works For Wisconsin

Economic Data

HUNTING IS PART OF WISCONSIN'S CULTURE

- **895,000 people hunt** in Wisconsin each year.

- **12 million days** are spent hunting in Wisconsin.

HUNTING SUPPORTS WISCONSIN'S ECONOMY

- Hunters support over **34,000 jobs** in Wisconsin.
- Hunting generates **$1 billion in salaries and wages**.
- Yearly spending by hunters in Wisconsin is **$2.6 billion**.
- The average Wisconsin hunter spends **$2,800 each year**.

HUNTING IS A KEY SOURCE OF TAX REVENUE

- Hunters generate **$228 million in taxes** for the state of Wisconsin.
- Wisconsin hunters pay **$263 million in federal taxes**.

WISCONSIN HUNTING: THE BOTTOM LINE

- The total ripple effect from hunting in Wisconsin is **$4 BILLION.**

The next area of consideration looks at depredation. This chart can be located at https://p.widencdn.net/7o52me/WolfDamagePayments

* Missing calves rule was in place limiting compensation to 5 missing calves for each verified depredation.
\# Indicates the number of that species compensation was provided on.

Depredation reimbursement started in 1982. Not until 2001 do we see an uptick in depredation, especially in livestock, but we also see this in regard to dogs. As reported in Wolf depredation on domestic animals in Wisconsin, *1916-2000, Adrian 'lkeues, Rarldle X..Jurcwicz. Lisa .\Talrglzton -Treues,Robert A. Rose, Robert C. CFTllging, and Adrian P. Weydeven*

"In Wisconsin, USA, over the past 2 *5* years, wolves have recolonized mixed forest-agriculture habitats range beyond public lands and recolonize agriculture and now number approximately 250 animals. Human-wolf conflict has resurfaced as a result."

Population size, pack size, normalization to people, and greater opportunity provide the axis for greater and greater depredation. These costs can be minimized if insufficient revenues from harvest sales occur however intolerance to wolves will accelerate and could provide impetus for lawsuits that in turn would be more costly to the state.

In the last few years we had a wolf visit our farm in Waukesha for approximately 18 months. She had three pups, reared them and I watched how she weaned them. She brought them to the edge of our hayfield and proceeded to cross over the middle. The pups would not follow. Within 30 days of that act one pup was hit and killed by a car and was confirmed 100% wolf. I reported this to the WDNR who scoffed, claimed they were coyotes until I described the size, then coydogs, and then wanted to know where I was trained in wolf identification at which point I suggested they come and observe from our dining room window as she was a frequent visitor. I heard laughter as they hung up. Recently 2022-2023 we heard a wolf howl.

Wolves follow the deer not the boundaries we place upon them and if unchecked or managed will adapt to every condition of the state. As more and more packs develop, individuals move to avoid conflict and will establish new ranges and to adapt to them. (Adrian P. Weydeven) The desire by some is to repopulate the entire historical range of the wolf.

Why is depredation and dispersal important? Wisconsin's primary business is agriculture and livestock, both beef and dairy.

Farms Operations[†]

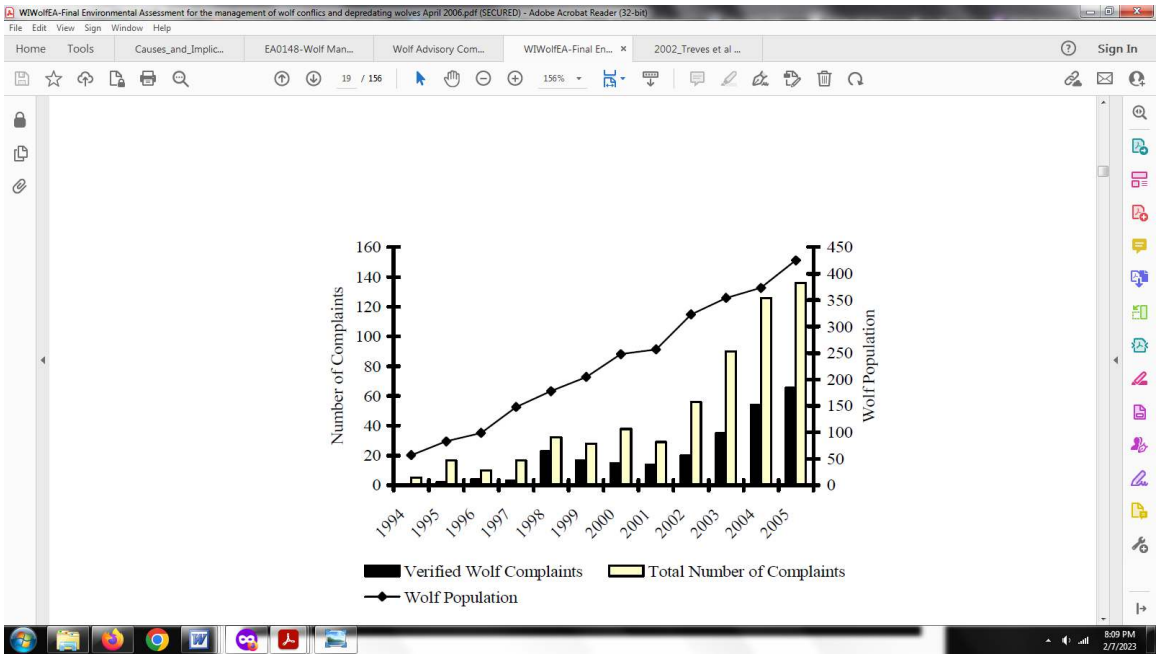
Farm Operations - Area Operated, Measured in Acres / Operation	222
Farm Operations - Number of Operations	64,100
Farm Operations - Acres Operated	14,200,000

A study conduct by UW Madison:
"Wisconsin's farms and agricultural businesses generate **$104.8 billion** in economic activity and 437,700 jobs, based on data for 2017, according to a new study from the University of Wisconsin–Madison. This is an increase from a 2012 study that found agriculture generated $88.3 billion in economic activity and 413,500 jobs in the state."

Our dairy industry Wisconsin's namesake:
"What percentage of Wisconsin's Agricultural receipts are dairy products?
Dairy products account for over 1/2 (54%) of Wisconsin's total agricultural receipts earning the state the #2 position among the states behind California for the production of dairy products."

Milk Production [†]

Milk - Production, Measured in Lb / Head	24,884
Milk - Production, Measured in $	5,959,976,000
Milk - Production, Measured in Lb	31,702,000,000



Stress in dairy herds will stop milk production and create conditions where cows will not impregnate. Loss of milk production will impact our cheese industry as well.

“The stress of predation by wolves can cause cows to lose pregnancies, **lower milk production** and lead to smaller weight gains, said Mattias Gugel, Tiffany’s

Livestock Inventory †

Cattle, Cows, Beef - Inventory (First of Jan. 2022)	295,000
Cattle, Cows, Milk - Inventory (First of Jan. 2022)	1,275,000
Cattle, Incl Calves - Inventory (First of Jan. 2022)	3,500,000
Cattle, On Feed - Inventory (First of Jan. 2022)	270,000
Goats, Milk - Inventory (First of Jan. 2022)	74,000
Sheep, Incl Lambs - Inventory (First of Jan. 2022)	82,000
Hogs - Inventory (First of Dec. 2021)	365,000
Chickens, Broilers - Production, Measured in Head	55,900,000

Wolf population increase by nature increases complaints, depredation, and intolerance.

Final Environmental Assessment For The Management of Wolf Conflicts and Depredating Wolves in Wisconsin, April 2006

Considering that the wolves inhabit approximately 25% of the state in 2022 and we see the cost in depredation accelerating as they expand is not a smart plan for Wisconsin or the wolf as they move deeper into more intensive agricultural areas.

Other positives I have heard regarding the wolf regard tourism where people will flock to hear wolves howling or perhaps even see a wolf. These are a few testimonials I have captured from people living in wolf country. One 64 year old woman jogging in white shorts and a white tank top had a revolver strapped to her waist. Not usually what one sees in jogger attire. I stopped to talk with her to learn why. She has a regular run she does everyday of nice weather. This particular day he caught movement coming through the woods right toward her and thought at first a deer. When she saw it her next thought was a dog but then realized it was a wolf. A neighbor who just happened by right then saw what was happening and had her get in their car. The wolf stopped and watched them for 20 minutes before heading off. She does not know what would have happened but carries the sidearm ever since.

Land o Lakes has invested in a bike path. A man was surveying it for a ride with his kids that afternoon when he saw three wolves heading right toward him. He accelerated and as he said fortunately he was faster on the bike. He did not return with his kids.

A bow hunter was preparing for the afternoon hunt. His last act of preparation was strapping a holster and pistol on his waist. Thinking he was not aware I suggested he not take the gun as the DNR will ticket him for carrying it while bow hunting. His response, "I don't give a F#&* what the DNR think. I have had so many issues with wolves I plan on always carrying. This is the third spot I have hunted to get away from them and they are everywhere."

In 1997 or 98 I saw my first wolf while deer hunting. It ran up and stopped 10 yards from me. We stood and assessed each other for a few minutes and then it left. A big beautiful grey. The next day my dad had it run up within 5 yards. He turned hearing it running thinking it was a deer upon which it pulled up short.

My recent experiences 2018-2021 have not been as wonderful. Walking to a stand one morning I saw three wolves coming toward me. I got to a clearing and watched as they circled. I could only see shadows in the moonlight. They finally departed and when I could no longer hear them proceeded toward my stand. I could hear them returning. I climbed the ladder and had them with me until 10:30 that morning. I left the woods when they departed.

The last encounter left me more rattled. As I still hunted to a location I knew about I saw 5 distinct wolf tracks in the sand. They were moving ahead of me. I got to where I wanted to sit and they were still moving along the road away to the west. I eased up along a ridge and was about to sit when a wolf west howled. This was answered to the east, north, and south in close proximity. I worked back to the road and headed to a knoll that provided good visibility. 20 minutes after taking up this position I watched a grey

and a black walk through the marsh. I left the woods. We saw no deer for the fifth year in a row.

These are not events that improve tourism. Many hunters I knew have gone south to hunt.

My goal is not to eliminate wolves in the state but to place them in a manageable number minimizing conflict. I am concerned that what we will see are more wolf attacks as experienced by Ray Calaway, Wood County having lost three guard dogs and 13 sheep.

As a livestock seed stock producer whose primary job is care, husbandry, and protection of our animals the idea of watching wolves tear into them and not allowed to do anything but watch is abhorrent as it would be to anyone. Reimbursement of loss of any one would be insufficient for the loss in genetic gain and uniqueness of 25 years of careful breeding.

With the uncontrolled population of wolves on the Indian reservation, 350 wolves to plan would provide all the benefits but minimize the damages and conflict. The idea that the state is even considering a taking of 6 miles around the Indian Reservation is baffling. The wolves like Yellowstone would have the protection of the Reservation. Should they move out of the reservation for some reason they become wards of the state and subject to the states rules. I suppose Indians could claim ceded rights but that involves harvest not mandating protection of certain species.

There are many reasons the state should abide by the 1999 plan of 350 plus or minus 10%. First, improve the opportunity of elk introduction. Second, restore conditions so that deer can recover and build the herds as CDAC's are working toward. Third, eliminate the threat to agriculture and livestock farmers and preserve the economic stability and ability to the state. Improve conditions for hunting not only for deer but all species such as Grouse that many who used to hunt in the state refuse to risk their dogs. It will allow tourism in the north as they work very hard to create economic opportunity to residents. And last it will reduce intolerance for wolves providing a successful path toward introduction.

The WDNR posts areas of the state that should be avoided because of wolf issues. Various surveys show that although most Americans value wolves, they do not do so to the exclusion of important human needs (Kellert 1986, 1987, 1999; Tucker and Pletscher 1989, Thompson and Gasson 1991, Wolstenholme 1996). Wolves Behavior, Ecology, and Conservation, Page 296.

MADISON, WI 53707-7921

February 28, 2023

JOHN MOODY
[redacted]
GREEN BAY, WI 54324

Dear Wisconsin DNR wolf management plan comment reviewers:
Read the entire 139 page wolf draft plan and here are my comments:

- Set a population goal
- Eliminate any buffer zone around Indian reservations
- Take action or Wisconites "will take matters into their own hands
  Wisconsin Motto "FORWARD" ie: Non action on feral cat issue years ago... haven't seen a feral cat in the northwoods since then.

As for Mission Statement: Full range of outdoor opportunities:

- Wolves @ boat landings (Tamarack Lounge, Vilas Cty numerous wolves carrying away goose gosslings)
- Wolf tracks + scat + sightings while trout fishing (lots of kids not carrying Concealed weapons permits, bear spray, airhorns or weapons)
- Won't hunt Alvin, WI area due to wolves surrounding vehicle upon return.
- Wolf didn't run away while performing annual cleaning of wood duck nesting boxes

Numerous other outdoor opportunities and license revenue lost due to wolf concerns detailed p.15 (wolf packs are capable of killing bear as large as adult females) LIABILITY IF ANYONE GETS HURT

Basically: In tune with The Wisconsin Trappers Association, Wis Bear Hunters Association and Wisconsin Wildlife Federation view points.

I am owner in part of the Northwoods, recreate there all year, responsible and good land stewards.

Sincerely, John Moody

cc: File

I'm writing in regards to the DNR wolf management plan. If the DNR knew anything about managing wolves, they would have a bounty on them to get rid of them. Back in the days of common sense, that's what our forefathers did, and it worked. After that we had no deer, cattle or hounds getting killed by wolves. And no thousands of dollars getting paid for wolf damage every year. The money paid is not enough anyway for a hound. You raise a young hound pup with your kids, and hunt it with your kids, and it becomes one of the family. Then it gets shredded by a pack of wolves and the DNR gives you $2500 for it. That's just as big a joke as the DNR itself.

The DNR is supporting liberal, anti-hunting, and environmental groups more than sportsmen and hunters. If the people would all get together and tell the DNR we're not buying a gun deer license until the DNR comes up with a wolf season, it would wake the DNR up. But, the people aren't that smart so it won't happen.

The DNR knows nothing about managing small game either. Back in the day there was a $20 bounty on coyotes and $5 on foxes. To match those bounties today it would be about $175 on coyotes and about $45 on foxes. Fishers and otters should also have bounties on them. The fishers got the snowshoe rabbits next to the point of extinction.

I want a response to this letter.

Gary Muench

Grey Wolf Facts

I attended all the early wolf information meetings on wolf recovery because as a Timber Manager there was talk of restricting timber harvesting in prime wolf habitat areas. Our company owned 40,000 acres in prime wolf habitat areas that had been managed for 80 years for hardwood sawlogs. After some studies it was determined that wolves' main diet is deer, and selective logging attracts deer, so the set aside was dropped. Then there was a proposal on how many wolves were needed to sustain recovery. If I remember right, I think the first number was 60 wolves in northern Wisconsin but from there the number kept rising until it was over 300, now we have 1500-2000.

Nobody at these meetings from northern Wisconsin was in favor of wolf recovery, but all the experts from southern Wisconsin felt we needed wolves up here. They told us that wolves howling would be music to our ears and the local businesses would fill their pockets from tourists traveling north to view and listen to wolves' howl. This turned out to be the exact opposite because once our deer herd was destroyed by wolves the businesses were empty during hunting season. As a matter of fact, a high percentage of northern hunters headed south or west to where there are some deer.

It is unsafe to take your bird dog or hunting hound in areas with wolves. A friend of mine in Laona had wolf tracks on his deck and one night his dog was barking by the patio door and there was a wolf two feet from his glass. Then a wolf bit and squeezed the cyclone wire on his dog kennel together but couldn't get in. His dog was outside later and went missing, never found. Another friend had a wolf dash out of the woods into his yard and grab his small dog in broad daylight and his wife screamed and it dropped the dog and after an $800 vet bill the dog survived. Many of my hunting friends have had dogs killed or injured while hunting.

Wolves don't only kill for food they just like to kill. Being out in the woods every day marking timber, cruising timber, or setting up timber sales for 45 years, it's easy to see what is going on. I've seen hundreds of dead wolf-killed deer on our logging jobs and a high percentage were killed and left to rot. Wolves very selfdom come back and eat deer they've killed the day before. Most wolf -deer chases are no more than 200 yards because a wolf can outrun the deer. These kills are very unsightly with a foot wide blood trail with these deer struggling for their life. A deer's only protection is running and the only thing that they can't outrun is a wolf. Where I hunt, the wolves howl at about 8pm to start the hunt, then they howl if they make a kill, or at 8 or 9 am when they return to get back together for the day.

There has been much misinformation as for historical number of wolves in the early days. (100-140 years ago) I had an old gentleman in the 1960's tell me around 1900 or before, some stray

dogs chased a deer into Crandon (Riggsville) and the deer was in such bad shape some men killed it with clubs. They hung it up on the main street in Crandon and he said people came from miles around because they had never seen a deer. I asked him if there were many wolves around at that time and he said no because there was nothing for them to eat. The deer started moving in when logging and farming began.

The point is the wolf experts say they want to restore wolves to their original numbers and right now we are 10 times over the original numbers. My grandfathers and great-uncles that worked in the woods and stayed in logging camps told me they never saw a wolf in their life. They said they heard a wolf howl occasionally. I have probably seen 20 wolves since the wolf recovery began and hear them howl almost daily. Wolves howl at noon whistles and police and rescue squad sirens during the day and night.

At one time Forest and Langlade counties had a half dozen of the best trappers around that made a living trapping for bounties and fur. I think a fox and bobcat bounty was $5.00, a coyote was $20.00, and a wolf was around $40.00. My uncle was one of these trappers and he would run a 25- or 30-mile trap line. If he caught 4 or 5 wolves a year, he felt he was successful- today he could probably catch 4 or 5 per week. He has told me wolves, if you could find one, were much easier to catch than a coyote or fox because they weren't afraid of steel trap odor.

In summary, something must be done to lower the wolf population in northern Wisconsin before they eliminate our deer herd. The few deer we have live by the road or around people's houses. In the deep woods, there are very few deer and in town it is almost impossible to grow a garden, apple trees, flowers, or shrubs in your yard due to wolves occupying the deer's preferred backwoods. Wolf management must be a commonsense program and NOT political.

Thank you,

Ken Mullins, Retired Woodland Manager

PUBLIC COMMENT: ***Wisconsin Wolf Management Plan – 2022***

As a master naturalist, I know that establishing and maintaining robust wolf packs have an invaluable, cascading effect within ecosystems. As a concerned Wisconsinite, I know that wolves have an inherent right to be here and to flourish or decline based on the vagaries of nature—not the whims of man.

Why were wolves the only species in Wisconsin being "managed" based on an arbitrary, bare-minimum number? We must learn to live with these apex predators—allowing nature to dictate their populations. There are too many unknowns for us to be establishing numeric population goals.

Having read Section 4 of your draft plan, I believe the plan has been well thought out and I appreciate the efforts of those who were involved in its detailed compilation. It took almost 25 years for this new plan—which is too long to wait again to react if the dynamics of climate change and biodiversity suddenly cause wolf populations to dramatically change. That's why this new plan must be adaptive and must also never be guided by politics or special interests.

I have also read parts of the *Draft Colorado Wolf Restoration and Management Plan* that will use science-based, adaptive and impact-based management as its basis. It will focus on minimizing conflicts, minimizing lethal take, and building of trust across diverse communities. Their plan acknowledges the critical need for long-term funding, as well as outreach and engagement—leaving wolves wherever they are if they are not causing problems.

Wisconsin will also need to consider funding. We need to research all non-lethal approaches to management—including wolf relocation into areas where they could flourish and become an integral part of another Wisconsin ecosystem (zone).

The fact that an irreplaceable keystone species was—and is, again—on the Endangered Species Act list indicates we have been doing things wrong.

We can assume that federal protection is unlikely to last forever. We must do our best to ensure that Wisconsin never gets caught up again in a cycle of protection, recovery, delisting, and overkill of one of Wisconsin's *gifts of nature*—the Gray Wolf. Your new plan appears to be a roadmap toward that goal.

Respectfully,

Deb Muraro

Wolf Comment:

Maintain a population of 350 Wolves in the State of Wis.

Scott Nordin
[redacted]
Shawano, Wisconsin 54166

January 6, 2023

WI Department of Natural Resources
101 S. Webster Street, PO Box 7921
Madison, WI 53707-7921

I have read the entire draft Wolf Management Plan and have submitted online comments to observe the format. Although it is obvious that your administration is not concerned with receiving public input regarding this plan, my concerns follow:

1. The draft plan, released the day after the election, reeks of partisan influence. Its debut is long overdue, intentionally to delay any potential harvest of wolves. The present administration has no desire to effectively manage the wolf population. They'd rather let the wolves manage themselves.

2. The online public comment is tailored to conform to the desires of the administration. Initially this was the only way to comment, excluding those without internet. The public survey included in the plan is completely biased, solicited to a majority of urbanites with no clue about nature except what they see, hear or read via the liberal media. Why are there no public hearings scheduled in wolf country where the people are most affected by this plan? Many counties have passed ordinances in support of a maximum goal of 350 wolves. Where is this covered in the plan?

3. My biggest objection is the lack of any population goal. Without it there is no accountability. You expect us to trust you to manage the population, but you've lost my trust. Your population estimate is way low. You only count packs, no dispersing wolves or lone wolves, no pups. By neglecting to include a population goal you have absolved yourself of any credibility. Your count prior to the 2021 hunt was 1126 wolves. Hunters/trapper harvested 216 in 48 hours. There is no way they could kill 19% of the population in that period. The population estimate was/is way low. Your plan is biased against hunting wolves with dogs. Why, because this method has proven to be efficient in reducing the wolf population? This method should be considered a valuable tool.

4. The plan calls for increased buffer zones, especially around tribal lands. I object to this. The tribes were consulted regarding the plan, but the local tax paying residents were largely ignored. Any agricultural businesses within these increased buffer zones will be adversely affected, as will the residents, their pets and livestock.

5. I have been hunting and trapping for more than 50 years. The overpopulation of wolves has decimated the deer population in the northwoods. The remaining deer are congregated near the cities and residential areas which provide some refuge. There are very few deer in the wilderness areas. The wolves are a big problem for coyote and fox trappers. My brother and I trap from Shawano all the way north to the Upper Peninsula. Wolves are everywhere in this range. Some of our best coyote areas have so much wolf sign we won't set traps. Even though we avoid areas with heavy wolf sign we still catch them in other areas. We caught and released 8 wolves the last couple years. They are a time consuming problem and safety hazard to release. They also kill/mutilate many coyotes and fox that are in our traps. Observed wolf sign in our trapping areas has continually increased but your population estimate remains stagnant.

Sincerely,

Scott Nordin

WI Draft WMP Talking Points

What we like:

We appreciate the efforts of all WDNR staff involved in updating the state's wolf management plan. Although we believe the current plan needs significant updating (see next section), we recognize the efforts and improvements made to the previous plan, including:

- Wolves in WI will no longer be managed by reference to the old numerical goal of 350 wolves.
- There is much greater recognition of the ecological role of wolves
- The inclusion of a social survey, which notes increased positive views of wolves, knowledge of their ecological roles and increased opposition to the motives and methods for killing wolves
- The adoption of proposed buffer zones around tribal reservations (i.e., previously no buffer zones existed)

What we don't like:

- The current draft does not reflect the best available science, and is missing a substantial amount of scientific literature on (see reference list below):
    - wolf ethology, sentience, sapience, sociability, agency and wellbeing
    - effectiveness of non-lethal interventions, especially relative to lethal ones
    - the impact of widespread killing on wolves' physiology, behavior, wellbeing, social dynamics, ecological relationships and evolution
- The above scientific omissions, combined with the emphasis on and promotion of sustainable recreational killing and consumptive users as a main management strategy, results in a biased plan that runs contrary to scientific evidence despite much of this omitted scientific evidence being more recent, numerous and of stronger inference.
- The plan should strictly curtail any lethal management of wolves except in extremely rare circumstances of immediate defense of life.
    - A substantial body of research documenting human-caused mortality in North American wolves, including Wisconsin wolves, has found that policies allowing liberalized killing of wolves result in a direct increase in the hazard and incidence of illegal killings.

    - Hounding or hound training, which are akin to allowing legalized dogfighting, should be illegal or severely restricted as this practice is extremely cruel to wolves and hounds alike and is not supported by the majority of hunters or the broad public.
- The plan should prioritize wolf protections and concentrate solely on non-lethal management of wolves in response to livestock conflicts to ensure ethical coexistence.
    - Despite Act 169, which mandates a wolf hunting season, the department can still restrict the implementation of lethal methods by setting minimal quotas, including a quota of '0' wolves, restricting timing and methods.
    - Several studies have proven a proactive non-lethal approach leads to better conflict mitigation.
    - Lethal management often fails to provide a long-term solution to wolf predation and has the least consistent success rates when compared to non-lethal practices. In addition, there is significant evidence showing that lethal wolf management may be less functionally effective at mitigating subsequent livestock losses than non-lethal deterrents.
- The plan should *require* the implementation of abatement measures as well as the use of non-lethal conflict minimization techniques by domestic animal owners for the latter to receive compensation for confirmed predation.
- The plan also runs contrary to public values towards wolves (and omits mention of such majority values from the plan), despite department surveys evidencing that the broad public cares about wolves as individuals (and not just for the viability of the population). Given the recent liberalization of killing wolves by the state, it would be incredibly informative to note majority support of the following reasons for opposing a regulated wolf hunting/trapping season (which are all omitted from the plan): opposition to specific methods of harvest like hounds (64%) or traps (70%), feelings that hunting wolves is unnecessary (62%) or culturally offensive to Native American tribes (57%).
    - All such reasons convey majority disagreement with practices currently promoted and endorsed by the legislature and the WDNR, and such a conflict between managers and the public should not only be acknowledged, but foregrounded and carefully considered in policy (instead of dismissed).
    - Such decisions to omit literature or downplay evidence (e.g., such as majority opposition to killing wolves and their reasons) are contrary to principles of scientific integrity (e.g., present all relevant scientific evidence to the public) as well as ethics (e.g., disguising ethical decisions, such as recreational wolf killing, as robustly supported by science).
- Conflicting agency objectives (e.g., optimizing public hunting and conflict mitigation) are not only not acknowledged, but even misunderstood as harmonious, against the body of scientific evidence. That culminates in the prioritization of consumptive values and policies; e.g., according to the body of scientific literature, use of lethal methods, and

especially public hunts, are contrary to most objectives relevant to: harm mitigation, the wellbeing of wolves, their ecological roles, and their non-exploitative enjoyment (i.e., Objectives A, B, D and F).

- There is a stark lack of consideration for individual wolves, wolf population health (including wellbeing), and measurable indicators for assessing any harms barring disease prevalence (e.g., accounting for cortisol levels or other stress hormones, measures of pair/pack persistence)
- There is an inappropriate understanding and consideration of tribal worldviews about wolves. Tribal worldviews of wolves are misconstrued as 'cultural benefits' tribes receive from the existence of a wolf population, when in fact tribal worldviews consider *each individual wolf* as a *person* and *relative*. Cultural respect and sensitivity towards such views, shared by many non-tribal members, demand the strict mitigation of lethal measures, especially recreational killing, as opposed to their current promotion in the plan.
- In general, all omissions of scientific literature, the arbitrary prioritization of policy objectives, the rhetoric of the plan and the dismissal of public values and concerns *for wolves* point towards a biased, unscientific and instrumental view of wolves that promotes values contrary to broad public perspectives on wolves.
- 'SOM' wolf estimation methodology – From a recent critique: "The new methods sacrifice precision, but are believed to retain adequate accuracy and sensitivity to changing conditions for reliable decision-making. We review evidence for the accuracy, precision, and sensitivity of the new 'scaled occupancy model' (SOM) applied in Wisconsin. We conclude that the Wisconsin method would systematically overestimate wolf abundance by large (but currently incalculable) margins. Because Wisconsin, similar to other states, not only changed to unverified methods but also implemented widespread wolf killing, shortcomings in their estimates of wolf abundance may have far-reaching consequences for population viability and confidence in state wildlife managers. We discuss findings from Wisconsin alongside similar findings for other states' occupancy models being insensitive to human causes of mortality that have recently increased. Overall, Wisconsin's proposed method for estimating wolf abundance shows significant departures from best practices in scientific measurement. Verification will require independent replication and unbiased tests at multiple scales in multiple habitats under different human-induced mortality rates, and peer review before the new methods are considered reliable." (Treves & Santiago-Ávila, 2023)

Rating: 4-5

To whom it may concern: (Wolf Management Plan Committee members)

I Find many flaws in the wolf management Plan you are currently proposing!

Some that are most concerning are:

- No triggers for population control
- having the sovereign nations having control over private property Rights, while not Allow lethal control as needed.
- Not Setting Cap Limit on population goal !! .... 36 County boards voted on 350 population CAP (no more)

Please Address these issues before you summit a final plan.

Thank you

Mike Racer

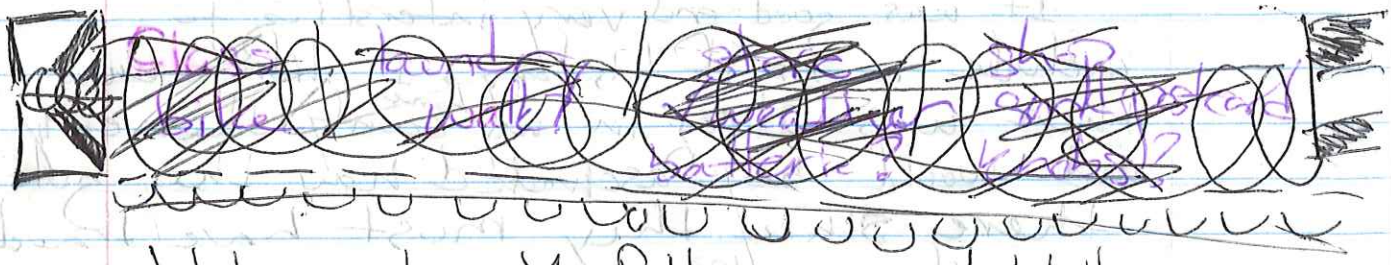
[redacted]

Wolf Mangement Plan Comment



I have read the current draft wolf managment plan as well as past surveys and sat through the recent verbal public comment session. I grew up in Lincoln county and my childhood experiance of going to the School Forest and going out at night in the winter to howl for wolves was so great I have to 'defend' that as something I'd hate to have people take away from future or current generations. I read they are going to stop doing howl surveys which makes sense because I bet that the wolves can tell when it's people or some played call repeated.

Lincoln county is in 3 zones. I feel these zones don't make sense a lot but similar to hunting areas in state parks that's what happens when politics override the science. Inherently when you put multiple zones crossing over various jurisdictions or area designations it makes it more complicated to enforce regulations. When you keep changing regulations and selectively enforce them even when documented you encourage things like cruel treatment, unethical poaching, & disregard to other people and animals that aren't being targeted in a 'hunt'. (1)

I would like to see money & personel go towards research and getting rid of invasive things not hunting on species the deer (P), one of which is despicable as well as being hybridable. Speaking of the hybrids I don't think they should be released but I think they should be allowed to exist but would discourage things like wolf dogs. It [illegible] my belief after reading & hearing several misinformed commenters that past survey's instead of a survey it'd be good if efforts were taken to educate the public about varias issues that range from the wolves are actually self regulating via the amount of food and territory available to the fact that in [redacted] the deer population is [redacted] more at risk from CWD, jerks in oversized trucks ticket time and harsh winter/spring weather. I also think it's fascinating that a lot of the reported wolf depredations were actually coyotes. I feel sympathy for people whose pets or livestock get harmed but would like to see people take practical measures to avoid wolves or other things instead of hunting or killing them maybe relocate or put in co breeding program It'd be interesting to take genetic data when trapped/survey etc.

(2)

~~Politics are inside policy making~~

Wolves haven't fully recovered, while robust resident population exists, I don't believe management approach is supported, ~~with~~ although this plan seems to allow for a passive do nothing and ~~maintain a current~~ approach which makes it less bias toward 'harvest'. The population estimate being a range instead of a minimum or maximum is probably a better more nuanced way to think of it.

[My notecard got out of order so the rest of this is maybe not in order but more specific to details of the draft plan.]

'Recolonizing' is perhaps a loaded term. Whether an animal (or plant) 'belongs' somewhere is 100% a weird human judgement, nothing else cares. Sometimes you should use different phrases for the public vs science however it's a deeper conceptual issue.

It was good and very interesting to include a breif history. I didnt know there was wolves in my former county that early and would be fascinated how they got there since they must have traveled a quite a distance.

If the expansion of territory has slowed (even though the population doesn't seem to effect that as much as other factors) hunting/killing doesn't reduce conflict.

'Public harvest' is an interesting term I would like to see replaced. I do think it's correct to differentiate between general public and say wildlife services killing animals. I also think this term is a false equivalence of how likely the general public at large is or would have any interest in killing wolves.

The deer hunters having misinformed negative opinions is contributing to the wolves that are poached during deer season as well as the overlap between wolf hunt and deer hunt.

I agree with the buffer zones around reservations, and zero quotas, and hope people would respect that.

Recommending higher killing rates in (1, 2, 5) is a bit too much. Isn't the point of the plan that it makes a system to make that decision not actual permanent recommendations?

I would like the whole plan/objectives to focus more on the future because it's easy to get stuck in past issues and ways of handling things.

All wolve deaths should count toward population (unscientific to not count those). May be a moot point because moving away from hard counts but it angers me that ecspecially poached wolves may not have been counted when making decisions.

If you must have a season of killing, then in order to keep it to the number it's probably best to make any license zone specific. I think the ratio of thinking 1 kill for every 10 license is obviously not accurate and part of how too many were killed.

I support shortening the time allowed

between killing and reporting it.

Using a 1992 Federal Level or 1997 for state levels is an outrageous at of date data or basis for anything except to explain the evolution of understanding those levels were wrong and we don't know what a stainable level or whole range is at this juncture is.

I would like to see protection of den sites and more monitoring of health/genetics if they seem fairly healthy in general. Maybe worth microchiping some instead of collars but that's different possible use and data.

Strategy A5 misstates clear as primary prey of all wolves which actually varies per your own citations within this report and scientific knowledge. I realize more than one person wrote this but might want to clear some of the contradictions or statements that reinforce bias and misinformation.

6

I enjoy Aspens but not sure I support planting more and managing things like the forest mix of plants for hypothetical gains in animals. With climate change it's hard to say what survival rates of anything especially plants will be. I think elk are delicates but they face same issues as deer and making more hunters would probably make more ill informed wolf haters. Spent too much on the elk that were brought in but I'm going to stay on topic because this is already long. Have a q if elk pop ↑ pack density may change

Elk pop not high enough threat

I would like to see maximum info sharing between various stakeholders, tribes, etc.

Product D1e: May I request a skull for my skull collection? Do I need a scientific collectors license to go with that?

Abatment: Most of the abatment seem to deter and from experience it's ted attract animals away from where they shouldn't be. collars/geofence permatic ⑦

I think it should be managed by Bureau of Endangered Resources not Bureau of Wildlife management as it's federal list (despited).

There seems to me to be a lack of data about traps/trappers.

They don't bring additional disease risk anymore than similar canine species would.

I want to say I'm not in favor of labelling hybrids harmful wild animals. They are unfortunate but if habituated to people or bred they should be allowed to roam 'wild' but shouldn't be automatically euthanized either.

I object to Objective C. Bias as there's no 'satisfaction index' or similar surveys of other groups of the public such as tribes or hikers or bikers etc. The 'conservation' models of the past/current favor hunting as a use even after historic levels of mismanagement and permanent damage. This creates conflict within management that funding is somewhat dependent on certain groups.

8

I'm highly against allowing bait especially anything that may be toxic to other animals. You disrupt feeding cycles and travel of multiple species. Make them associate food with people.

Think the punishment for poaching any animals should be higher. I see voluntary compliance stated multiple times but it shouldn't mean ignoring indicators of future infractions/current ones. It's hard to police the entirety of the outdoors but seems that certain crimes should be considered more seriously.

I find it abhorrent people would use dogs to hunt dogs. Don't support a trailing season for that obviously.

Expanding territory and being generally healthy indicates they haven't reached a maximum population

Hunting in state parks is not maximum benefit to all users and wildlife. The 3R model that neglects hikers, bikers, beach goers, campers etc. You mention funding increase shooting ranges but not making more campsites or upgrading them or ancillaries. They bias appointments to committees will continue bias in use but it seems to be failing.

I don't support any night hunting. It's less safe and may encourage poaching as well as failure to registers.

If there is a hunting season please use a complete unbias lottery (no points or state vs non residents).

Don't think the public has a good grasp of issues such as habitat fragmentation, expansion and density of either the wolves or anything else frankly. Don't know it would change most opinions though. Education should focus on general issues more than complicated models etc.

I think referring to wolf range or non wolf range as to survey opinions to label people just reinforces the notions there's a part wolves are 'occupying' & that it's permanent, or there's a part they won't or aren't (known) to be in (or could). It's not statistically significant and according to your own statements it doesn't help predict people's opinions, yet creates unnecessary divisiveness people try to use to manipulate.

Framing, stereotypes, narratives are long held and are hard to annihilate. Letting people express themselves in public comments is great but I'd like to see some correction when they make highly infactual comments. Everyone is entitled to their own highly even wrong opinion but never miss a chance to give some brief factual push back on wrong facts please.

'Interesting' doesn't belong in front of 'pre' and 'post event assessment'. Not a great word choice for poorly regulated hunting of an animal that was recently almost killed to the point of extinction and intensively

(11)

It appears there's more concern about opinion then actual data and concern about science and environment in totality. I support engagement and education of the public while we acknowledge that the public is not always equal weight in decisions to people who have to implement and understand what's going on. Bias in who bothers to get involved in committees or comments.

'Regulated harvest' should be state sanctioned depletion of natural resources for personal profit unscientifically supported but politically mandated by at all state 'hunters' and gerrymandered politicians killing time.

Hunt is likely to disturb full range utilization and establishment of maximum capacity which will possibly risk population collapse/general instability, and increase conflicts and poaching.

12

I support more funding for land bridges s. wildlife and people can avoid roads/vehicle collisions. Don't think the building should be the dept but research should happen & help DOT etc with planning.

ESC: Fine but as 'general' 'opertunistic' by definition they will live everywhere they can manage to.

For an example of your 'At Large' committee appointee you cited a hunting group. So umm you doing the blab thing.

Shouldn't do CITES. Do you really need more paperwork? It takes resources away from state.

Cougar(s) is irrelvant to bring up unless it's addressing the ones known to be in the state or near by enough they roam in/through. If wolves effect establishment of territory vs keeping them moving or vis versa.

Thank you for extending the commenting period, and your welcome for adding to the legitmacy of your process.

To the DNR - Wolf Management.

I have read about the controversy surrounding managing the wolf population in Wisconsin in Wisconsin outdoor News. It seems there are lots of opinions, many offered by people who are not affected by the presence of wolves - such as I. But it also seems that volume is important in guiding DNR decisions. So even though I don't think you ought to listen too closely to people who don't live with the wolves, I feel obligated to express my opinion

I can't understand how the DNR can manage the population of a game animal without having an accurate idea of how many of those animals are in the state - which I don't think you do - or without having a population goal in mind. How can it possibly be determined whether you are properly managing the resources?

I know there are many directions in which the DNR is pulled by this interest group or that. You're never going to make them all happy - but the one thing you can do is have solid data to use to drive your policy to a goal so that you know when it's been achieved - & you

option for a mandated Wolf Hunt.

We need a healthy wolf population to balance out our over abundance of deer (+coyotes?).

The last mandated hunt was a disaster, resulting in overkill and embarrassment. We do not need a mandated wolf hunt. Thank you!

My Comment on the Wolf Management Plan, 2023 in Wisconsin

To the Wisconsin DNR:

Thank you for your hard work + dedication. I believe the plan tries to address all the issues in a balanced and fair way - However - I do not agree with the

Dear Sirs:

I understand after reviewing portions of your Wolf Management Plan, that a mandated Hunt is an option that is included in the Plan.

I oppose a mandated Wolf Hunt in the State of Wisconsin.

1. It is not necessary.
the people of Wisconsin want a healthy wolf population.
We have an overpopulation of deer, which has been troublesome for many.
Wolves can help stabilize our deer populations (coyotes as well) and bring about a greater abundance of wildlife.
about a greater abundance of wildlife.

Yellowstone in 1995 has proven to be one of the most successful Wildlife experiments. It resulted in reducing the elk populations which had been overgrazing the park, but the effects were even more important to biologists. The Ecosystem recovered, but the rivers, forests and the landscape - recovered. (https://www.bbc.com)

2. We have options for compensation if Wolves predate on livestock. Compensation for farmers - along with education (starting in grade school - & other public venues) can help to create support for a healthy wolf population.

3. The last Wolf Hunt mandated in Wisconsin resulted in a very unfortunate surplus of dead wolves. That was not only unfortunate, but counterproductive in bringing our ecosystem into balance. It went in the exact opposite direction and was a public embarrassment. That should not be repeated. In summation: Delete the mandated

understand the DNR is charged with producing a document that is scientifically and socially acceptable. By an intentional and well planned public awareness initiative, I believe the DNR can accomplish a plan which benefits the citizens of the state & reinforces our need for a balanced ecosystem. We have an abundance of deer in the state that can be managed by a healthy wolf population. No hunt is needed. I thank the public servants of our state for their dedication and hard work.

Sincerely,
Florence Sandok

Wisconsin Wildlife Federation 2·22·2022
P.O. Box 7921
Madison, WI. 53707-7921

Wisc. Dept of Natural Recroos,

Its time to get these Wold Studys over with.

I have hunted 16 Western and Southern states and have read these studys for over 50 years. I am 82 years old.

Every state has almost the same answer to things that don't change from state to state

Like every Wolf needs the equivalent of a deer every 5 to 7 days. This has been the same to a long long time. Most range patterns, what there hunting pattern and distance is does not change.

These studys should be done a long-long time ago including how many Wolves there are

I have had a large pack of hounds since 1959 and have spent a large amount of time in the Woods.

I've hunted 16 western States all of Canada, Alaska, Mexico, Russia and Mongolia - I do have a background on what is going on outdoors. We do have an over population of Wolves in Wisconsin. You will never get ahead of them.

Sincerely
Paul W Schroeder

Wolf plan comments

After reading and rereading section 4 it is quite obvious the plan was written by wolf lovers for wolf lovers which Randy Johnson is one of them.

Without any numeric population goal, there is no accountability in the plan. Everything is left up to the wolf loving DNR biologist, tribes, and their wolf loving committee.

As I see it, the plan is to let the wolf population increase way beyond its current population which is way too high now. I suggest you do something to get the maximum population down to 350 wolves in the state, not letting the wolf population run wild like it is now.

Another thing the subzone around reservations is nothing but a big cop-out to the tribes. These subzones should be treated the same as the main zone. Maybe the tribes should fence the reservations to keep their wolves on tribal land. Then they would not have to worry about any of their wolves being harvested.

This is not a plan, but an insult to the people that live in the north woods. It is a farce with no intentions of decreasing the number of wolves in the state.

The December 16, 2022 issue of the Wisconsin Outdoor News has two articles in it one by Dean Bortz "Conservation Congress, WWF oppose wolf plan" and the other "Commentary" by Laurie Groskopf. You may want to read them; you may learn how people other than wolf lovers feel.

In summary, section 4 of the plan should be put in the trash can and a plan with some accountabilty and population numbers be developed.

February 17, 2023

To whom it may concern,

I believe there are 2 major aspects of the proposed wolf management plan that need to be resolved before any plan is adopted. These aspects are:

- there are no triggers for population control of the wolves in Wisconsin.

- there is no set number as a goal for wolves in Wisconsin.

There needs to be a set population goal and triggers with actions to maintain that goal.

Sincerely,

Ed Smoe

FEB 17, 2023

TO WHOM IT MAY CONCERN,

REGARDING THE PROPOSED WOLF MANAGEMENT PLAN, I HAVE TWO ISSUES THAT I FEEL NEED TO BE ADDRESSED.

1) THERE IS NO SET POPULATION GOAL FOR WOLVES IN THE STATE. SIXTY NINE COUNTIES HAVE VOTED ON A GOAL OF 350 WOLVES, THESE COUNTIES NEED TO HAVE THEIR CONCERNS HEARD

2) THE PROPOSED PLAN LIMITS PROPERTY RIGHTS OF PRIVATE PROPERTY OWNERS BY AFFORDING CONTROL OF WOLF POPULATIONS TO SOVEREIGN NATIONS, WHEN WOLF TERRITORIES COVER BOTH PRIVATE LAND AND LAND BELONGING TO SOVEREIGN NATIONS.

I REQUEST THAT THESE TWO ISSUES BE ADDRESSED BEFORE ANY WOLF MANAGEMENT PLAN IS ADOPTED.

THANK YOU,

Fran Snow

2/17/2023

To whom it may concern;

After reading the proposed wolf management plan, there are several issues I feel need to be resolved.

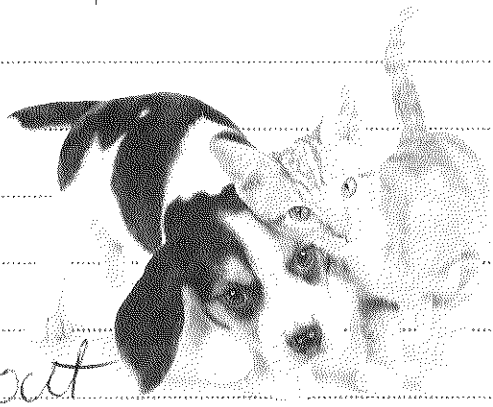
- Private Property rights. Wolf population control should not grant sovereign nations control over private lands owned by citizens.

- Population Goal. There needs to be a solid, published number for a wolf population goal in the state. This number should be based on biological and cultural carrying capacity.

- Population Control Triggers. There need to be clear triggers for wolf population management within the state.

Please address these concerns before accepting a wolf management plan.

Thank You,
Kyle Snow



Jan 20 2023

To WDFW management,

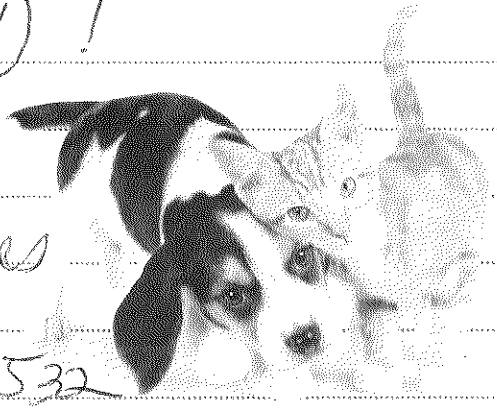
I do not understand you people out west. Why you want to kill all the wolves

If there are no wolves the whole eco system will feed animals who are sick will get others sick. wolves take out the sick and the old.

You people need to Rethink your decision about

wolves

God made these creatures for a Reason.



NOT for them all to be slaughtered away.

They serve a great purpose in this world.

The worse killer and destructer is

MAN!

Sincerely
Cathy Stanwicks

Dear Wis. DNR:

I just want to expess my disappointment in your new wolf plan. It is very poorly thought out and very incomplete. It does not address all the problems the wolves have created. The DNR needs to listen to the people who live in wolf areas and needs to listen to the Wis. Wildlife Federation.

Thank You

G W Sutherland

Comments DRAFT 2022 Wisconsin DNR Wolf Management Plan

Richard P. Thiel

[redacted]

Tomah, WI 54660

1. (Page 4) Habitat Use and Requirements –
A. No mention is made of *Simpson 2019* CFR demographic analyses on wolf responses to habitat quality. Her work is ground-breaking and conducted within Wisconsin and should not be overlooked. A paper submitted to the Northeastern Naturalist was just accepted. Her work has direct implications when considering / constructing harvest quotas because, as she demonstrates, habitat quality impacts wolf demographics positively and negatively.
B. As written, this DRAFT plan delineates a more conservative management approach in the state's "core" wolf habitat: Zones 1, 2 and 5. Core habitat is the equivalent to Optimal and Mixed Habitat types described by *Simpson 2019*. Referring to her work adds scientific merit for a more conservative management approach in these core habitat zones.
2. Harvest Management & Total Allowable Take (TAT) -
A. I notice that this plan does not go into great detail on techniques that are applied to harvest management. Perhaps this is intentional.
B. Total Allowable Take - Practiced for uncommon, low density and rare species that are harvested (examples - grizzlies in Montana in the 1970s; polar bears currently), it is not readily apparent to the general public (and perhaps some biologists). This concept of harvest management is implicit in the DRAFT plan, but not given proper relevance in its application to the proposed management of wolves in Wisconsin. It certainly applies to Wisconsin wolves. TAT takes into consideration all known mortalities (depredation control take, vehicle, known illegal, natural causes, etc.), and evaluates this against the maximum number of animals that can be safely removed from the population without causing a decline. For wolves this is generally somewhere around 25 to 30 %, although scientific uncertainties on this maximum figure exist. I recommend a conservative approach, especially in establishing quotas in Zones 1, 2, & 5.
As an example of TAT - when all mortalities, combined, exceed 25% of the previous winters' population estimate for that zone, the harvest quota would be ZERO. This approach avoids the potential that a harvest becomes an additive source of mortality.
In Zones 1, 2 and 5 - as stated in the plan - a conservative approach is recommended. Applied, I recommend a TAT in these zones never exceed 10% of the previous winters' population estimate. Conversely, in agricultural areas subjected to chronic depredations - and in zone 6, a very liberal quota could be established, since the objective is (a) keep wolves from establishing breeding groups here, and (b) reduce existing numbers because of inordinately high levels of conflict with humans in this zone.

3. Hound Training Period Page 127 – Product c2h – pursue admin rules allowing same. I am against provisions establishing a hound training period for wolves for 3 reasons: (1) ample training is already in place and in practice by a portion of this specialized hunter community coincidental to the bear training season – and the warden force provides no meaningful enforcement against such wolf-chasing practices, (2) in an already crowded calendar of harvest

related activities on public lands, when would such an activity not conflict with these and others rightful use of public lands (non-consumptive users should also be considered in this), and (3) public sentiment opposes this (unfortunately, not that the agency has ever really cared to recognize this).

This plan should outline elements of Act 169 that are recommended for change, returning to the agency greater and rightful exercise in managing the state's wolf population. Such things as season length, legal manners of take, authorizing the agency to determine when/whether a harvest is recommended (rather than statute's present mandatory mandate), etc. should be returned to DNR.

4. Page 141: Product D1e – Use of wolf specimens. A specified percent of wolf carcasses should be offered to research and scientific museums annually to provide time-specific specimens for use by the scientific community *ad infinitum.* As presently stipulated, no *real* motivation exists to supply specimens. These collections are of benefit to future researchers. A number of museums - private and public - exist within Wisconsin and regionally (ex. Chicago's Field Museum) should be approached and agreements should be completed.

5. Page 115 – 122 Objective B – Wolf-human conflict – No provision is made for, or mentioned regarding the continuance of landowner shoot permit. Is this being considered or is it being discontinued? This provision was lauded by those of us who implemented it in the field as "giving power back to the people", reducing the angst against what is perceived as governmental interference in a person's individual rights to protect property, etc. etc. It did not result in huge numbers of wolves taken, but did bring landowners relief, returning some respect for the agency. I recommend provisions for this program be returned to the tool-box in dealing with livestock depredations.

DT 30 Jan 2023

Thanks for reading public comments on your proposed policy changes. Please draw on the citations and logic below, which represent my interpretation of evidence relating to various issues in the wolf science-policy interface.

I support the elimination of the ill-conceived population goal of 350 wolves in late winter of the 1999 plan. I support continued use of winter snow-tracking because field-based ground-truthing is the only way to sort out the mess created by the inappropriate use of the scaled occupancy model explained next.

My biggest concern about the WDNR wolf management plan is the proposed use of the scaled occupancy model (SOM) to estimate statewide wolf abundance. With Dr. F.J. Santiago-Ávila, I have found five major shortcomings in the WDNR use of the SOM that each lead to over-estimation bias. I describe the five shortcomings below but first the implications. The bias we found in methods used by the WDNR means the 2022 estimate of the state wolf population is an over-estimate by a large margin. Future use of the SOM in such an unscientific and inaccurate manner makes all future population estimates suspect. The risk of such bias is to place the wolf population in jeopardy if a wolf-hunt is ever held again. Therefore, based on the science and without remedy, I predict the next wolf-hunt will lower the state wolf population to the statutory listing level or lower (Treves A & Louchouarn NX. 2022).

5 major problems with the WDNR SOM and the application of Stauffer et al. 2021:

1. Unprecedented two winters of snow-track surveys included in the 2022 population estimate, spanning Dec 2020-Feb 2021 and Dec 2021-April 2022. This means dead wolves were likely counted towards the probability of occupancy by wolf packs.
2. Models of past wolf occupancy were validated on data 2-5 years after the last wolf-hunt not 1 year after. That makes the 2022 application invalid.
3. Models of land cover were from 2016 and insensitive to increases in human-caused mortality (e.g., Feb. 2021 wolf-hunt, both legal and illegal killing, and summer 2021 USDA-WS killing). That makes Stauffer et al. 2021 invalid today. Its occupancy probabilities need appropriate validation with more recent data.
4. WDNR abandoned quality control standards for snow-track surveys that had been in place since 2000-2004. By using data from surveys blocks that were snow-tracked zero to two times, the WDNR likely included lone wolves, transient wolves, non-wolves, and erroneous counts of wolves for calculating occupancy probability.
5. Pack size and territory size were based on small samples that were not representative of the whole state yet were extrapolated across the state.

Our papers are available for free (Treves & Santiago-Ávila FJ. 2023. Estimating wolf abundance with unverified methods. Pre-print free at http://facultynelsonwiscedu/treves/pubs/Treves_Santiago-Avila_critique_of_WDNR_2022-2023_SOMpdf http://faculty.nelson.wisc.edu/treves/pubs/Treves_Santiago-Avila_critique_of_WDNR_2022-2023_SOM.pdf and Treves A and Louchouarn NX. 2022. Uncertainty and precaution in hunting wolves twice in a year. *PLoS One* **17**: e0259604. 10.25.465697https://journals.plos.org/plosone/article?id=10.1371/journal.pone.0259604). Please note that if you do not click and download this free pre-print, I will assist any who would hold the WDNR accountable for collecting and reviewing the public administrative record. If you attempt to justify ignoring our evidence because it is currently a pre-print under review by a scientific journal, I hereby notify you that I post all published papers freely on my website and by the time you read this the paper is likely in print. Contact me directly at [redacted] if you cannot find the published version. Finally, if you attempt to justify your approach to the SOM by simply citing Stauffer et al. 2021, I will expose the undisclosed competing interests behind that article and the fact that the Journal of Wildlife Management was not signatory to the Committee on Publication Ethics until 2022, and is therefore not a well-regarded or reliable journal. Furthermore, please note the WDNR application of the SOM violates the steps required by Stauffer et al. 2021 to apply their model

scientifically. Therefore, I recommend fixing your unscientific application of their work, following our recommendations, and aiming for the best available science.

Above and beyond the problems we have found in the WDNR use of the SOM, this commentary addresses common policies and claims made by wildlife agencies about their jurisdiction's wolf populations. I have attempted two steps: (1) disentangling value judgments from scientific claims, and (2) my perception of the consensus in the scientific community if any. Paraphrasing Oreskes 2019: No single study should be considered reliable, even replicated studies await consensus in the scientific community, and only qualified experts with a track record in the particular field can weigh in on that evidence. Sometimes it is too early to claim consensus and sometimes consensus in the scientific community should be reached but the intrusion of claims by those who have financial or non-financial competing interests will distort or delay scientific consensus and its application to policy. Therefore, I offer below my own view of consensus within the scientific community about several bodies of evidence in the wolf science-policy interface. Where I cannot find consensus I try to illuminate the standards of evidence one should employ to weigh contrasting research and select the best available science.

Section 5 addresses scientific integrity requirements under US federal law and the potential legal jeopardy for lower jurisdictions receiving federal funding that do not adhere to federal rules on research misconduct. Here I am primarily concerned with the breach of scientific integrity represented by selective citation of articles that support the predetermined policy outcomes. See the recommendations ons scientific integrity from the National Academies of Science (NAS 2017. Fostering integrity in research. Washington, DC:) The National Academies Press), which states, "…careless or negligent crediting of prior work violates the value of fairness" p.36, https://doi.org/10.17226/21896 . Moreover, many scientists view selective citation as misconduct, e.g., see this Science article for the data supporting that claim De Vrieze J. 2021. Landmark research integrity survey finds questionable practices are surprisingly common Science 7 July 2021 https://www.science.org/content/article/landmark-research-integrity-survey-finds-questionable-practices-are-surprisingly-common. Beyond selective citation, the WDNR has an issue with transparency in data sharing, disclosing assumptions, and clearly explaining methods. I direct them to the following articles explaining objectivity in methods and assumptions: Treves et al. 2021. Transparency about values and assertions of fact in natural resource management. Frontiers in Conservation Science: Human-Wildlife Dynamics 2: e631998. 10.3389/fcosc.2021.631998. & Treves A. 2019. Scientific ethics and the illusion of naïve objectivity. Front Ecol Environ 7: 361. doi:10.1002/fee.2091. & Treves A and Santiago-Ávila FJ. 2020. Myths and assumptions about human-wildlife conflict and coexistence. Conserv Biol 34: 811–818. 10.1111/cobi.13472. & Treves A. 2022. Best available science" and the reproducibility crisis. Front Ecol Environ 20: 495. 10.1002/fee.2568.

1. Population viability assessments (PVAs), minimum viable populations, and strict numerical delisting targets.

First and most importantly, value judgments arising from personal, organizational, or governmental commitments, investments, and preferences for certain outcomes are the first steps in PVAs because the following inputs or decisions are value-based choices not scientific decisions: (A) how far ahead in time should one forecast (e.g., perpetuity or a few years, see Frankham et al. below for preserving evolutionary potential and consider whether the jurisdiction is fulfilling the trustee duty to preserve the asset for future generations); (B) how much risk of extinction is the public willing to tolerate and how much is the agency allowing? (e.g., near zero? Or a predetermined level of risk?). (C) Did the modelers exclude any threats (e.g., super-additive mortality from human-caused killing, illegal killing, catastrophic disease)? (D) Most PVAs risk being misapplied to jurisdictions rather than to actual biological populations. (E) The decision to focus on census population size (all individuals) or effective population size (Ne, shorthand definition is all breeding individuals). Each address different aspects of viability. The

former addresses demographic viability without guarantees that the surviving animals will be healthy and reproducing effectively, whereas the latter is more precautionary and addresses evolutionary potential. If evolutionary potential is preserved, one can generally assume demographic survival has also been preserved. In wolves, where virtually all packs contain only two breeders, effective population size can be estimated by the number of packs in one year (although this too may be an over-estimate because not all pairs breed each year) but the rest of the population provides a source of new breeders to replace those that die.

References and notes for section 1 only

Consider the distinction between science-informed decisions and making decisions based solely on science from the quote from Vucetich JA, Nelson MP and Phillips MK. 2006. The normative dimension and legal meaning of endangered and recovery in the U.S. Endangered Species Act. Conserv Biol 20: 1383-1390. “The ESA’s requirement that endangerment be determined ‘solely on the basis of the best scientific and commercial data available’ does not mean scientists have exclusive right to determine the normative dimensions of specifying the conditions of extinction. This mandate merely provides science the exclusive right to determine whether specified conditions for endangerment are met by particular species.”

Carroll C, Lacy RC, Fredrickson RJ, Rohlf DJ*, et al.* 2019. Biological and sociopolitical sources of uncertainty in population viability analysis for endangered species recovery planning. *Scientific Reports* **9**: e10130. https://doi.org/10.1038/s41598-019-45032-2. Abstract: Although population viability analysis (PVA) can be an important tool for strengthening endangered species recovery efforts, the extent to which such analyses remain embedded in the social process of recovery planning is often unrecognized. We analyzed two recovery plans for the Mexican wolf that were developed using similar data and methods but arrived at contrasting conclusions as to appropriate recovery goals or criteria. We found that approximately half of the contrast arose from uncertainty regarding biological data, with the remainder divided between policy-related decisions and mixed biological-policy factors. Contrasts arose from both differences in input parameter values and how parameter uncertainty informed the level of precaution embodied in resulting criteria. Policy-related uncertainty originated from contrasts in thresholds for acceptable risk and disagreement as to how to define endangered species recovery. **Rather than turning to PVA to produce politically acceptable definitions of recovery that appear science-based, agencies should clarify the nexus between science and policy elements in their decision processes**. The limitations we identify in endangered-species policy and how PVAs are conducted as part of recovery planning must be addressed if PVAs are to fulfill their potential to increase the odds of successful conservation outcomes.

Frankham R, Bradshaw CJA and Brook BW. 2014. Genetics in conservation management: Revised recommendations for the 50/500 rules, red list criteria and population viability analyses. *Biol Conserv* **170**: 56-63. https://doi.org/10.1016/j.biocon.2013.12.036 Abstract: Conservation managers typically need to make prompt decisions based on limited information and resources. Consequently, generalisations have essential roles in guiding interventions. Here, we (i) critique information on some widely accepted generalisations and variables affecting them, (ii) assess how adequately genetic factors are currently incorporated into population viability analysis (PVA) models used to estimate minimum viable population sizes, and (iii) relate the above to population size thresholds of the IUCN Red List criteria for threatened species that were derived from genetic considerations. Evidence accumulated since 1980 shows that genetically effective population size (*Ne*) = 50 is inadequate for preventing inbreeding depression over five generations in the wild, with *Ne* ⩾ 100 being required to limit loss in total fitness to ⩽10%. **Further, even *Ne* = 500 is too low for retaining evolutionary potential for fitness in perpetuity; a better approximation is *Ne* ⩾ 1000. Extrapolation from census population**

size (*N*) to *Ne* depends on knowing the ratio of *Ne*/*N*, yet this information is unavailable for most wild populations. Ratio averages (~0.1–0.2) from meta-analyses are sufficient, provided adjustments are made for dissimilar life histories. Most PVA-based risk assessments ignore or inadequately model genetic factors. PVA should routinely include realistic inbreeding depression, and genetic impacts on evolutionary potential should be incorporated where appropriate. Genetic generalisations used in conservation, the treatment of genetics in PVAs, and sections of the IUCN Red List criteria derived from genetic considerations, all require revision to be more effective conservation tools.

Finally, the selection of a specific numerical target or even a range of targets presumes a value judgment at some point in the process. For an explanation of how this plays out in sustainable harvest models applied to wolves, please see Treves A, Paquet PC, Artelle KA, Cornman AM, et al. 2021. Transparency about values and assertions of fact in natural resource management. Frontiers in Conservation Science: Human-Wildlife Dynamics 2: e631998. 10.3389/fcosc.2021.631998.

2. Are lethal methods *valuable* tools in the toolkit to prevent adverse predation by wolves? (* you can replace valuable with other value judgments such as best, essential, necessary*)

None of the terms surrounded by * are scientific in this context, they are all value judgments. A scientist would write lethal wolf control is a tool in the toolkit. The adjective is a flag that someone is attempting to impose their values on their readers. A scientist would add the adjectival phrase "effective to achieve x" or "ineffective to achieve x" or related measurable criteria that do not presuppose a normative judgment about whether one should use lethal control (as do the * adjectives). Note the word control can be misleading if not defined as it may convey to some audiences that prevention has been achieved even when it has not.

In most cases in wolf policy, effectiveness of lethal or non-lethal methods is oriented to reducing future losses of domestic animals or wild animals. Starting with domestic animals, beware of certain value judgments inherent to this question: (A) do the domestic animals or wild ungulates take priority over wolves, especially when lethal control is envisioned? That would also be a value judgment. (B) Also beware of the value judgment that all lethal methods can be meaningfully grouped into a single category. Scientifically, neither lethal nor non-lethal interventions can be grouped for a claim of effectiveness because each variety and each implementation may differ from the next in effectiveness based on design, location, conditions, effort, etc. Only when followed by the details of studies of effectiveness can one group two or more methods together to make claims (i.e., the advocate for either needs to anchor their conclusion about a method in a study specific to that method). (C) Some methods for protecting domestic and wild animals from wolves are in a gray area between lethal and non-lethal. This and other false dualisms are common in this field. (D) Effectiveness as I have defined it above has no spatial or temporal specification but should. No method is always effective, therefore the claim of effectiveness should be applied to a particular time, place, and design of the intervention. When scientists communicate clearly, we cite a study when making such a claim. All implementations are experiments, no single study will predict with perfect certainty whether a new application is effective. (E) Another subtler value judgment is whether the effectiveness of lethal methods and effectiveness of non-lethal methods are commensurable, because the effects of one cannot be reversed while the other may be.

Given the caveats above, single studies are no basis for confidence until replicated. Therefore the methods that have been replicated by two or more studies show they are effective should give the most confidence. Therefore, systematic reviews or meta-analyses are our best basis for predicting whether a given intervention is effective. Even systematic reviews and meta-analyses

are prone to error if they have a small sample size to draw from, authors have competing interests, or the analysis did not consider strength of inference.

The strongest inference is drawn from randomized, controlled trials (RCTs) of methods to prevent predation on domestic or wild ungulates. Preferably those RCTs include crossover designs, blinding, and are subjected to authentic independent review and efforts at replication. The next and much lower strength of inference is the silver standard of before-and-after comparison without randomization. That is the highest standard reached for lethal control of wolves and was only reached in 3 studies to my knowledge (see figure below).

Michigan USA: Santiago-Avila FJ, Cornman AM and Treves A. 2018. Killing wolves to prevent predation on livestock may protect one farm but harm neighbors. *PLoS One* 13: e0189729 10.1371.
France, 9 regions: Grente O. 2021. Présentation des objectifs et de la méthodologie de la thèse sur l'efficacité des tirs de loup et la gestion adaptative du loup, menée conjointement par l'oncfs et le cefe. Gières, France.
Slovenia: Krofel M, Černe R and Jerina K. 2011. Effectiveness of wolf (canis lupus) culling as a measure to reduce livestock depredations. *Acta Silvae et Ligni* 95: 11-22. (Note the data from this study were reanalyzed in a silver-standard design by Treves, A., M. Krofel, and J. McManus, Predator control should not be a shot in the dark. Frontiers in Ecology and the Environment, 2016. 14: p. 380-388.)

In the below graphic, I summarize the three studies' findings on the effects of lethal methods on wolves but again note that we still have no RCT on killing wolves to protect domestic animals and note the methods for killing wolves in the three studies differed somewhat.

My co-authors and I do not consider the analysis by Bradley et al. (2015) in the Journal of Wildlife Management to be reliable because (a) the authors could not explain several steps in the methods to us, (b) they did not share the data for us so we could use our own methods, (c) their methods biased the results toward favoring lethal control by extending the time horizon for livestock losses beyond the point where wolves held a territory. Thereby, they counted vacant territories as if territories can kill livestock, rather than packs. Their approach seems analogous to a study of a hospital treatment that measured filled and vacant hospital beds rather than the survival or death of patients) - see detailed explanation and discussion in Santiago-Ávila et al. 2018. Furthermore, the journal in which Bradley et al. 2015 was published, only subscribed to the Committee on Publication Ethics (COPE, https://publicationethics.org/) in 2022: Krausman PR. 2022. Improving the journal of wildlife management: A response to the perspectives of Johnson et al. (2021) and Gould et al. (2021). *The Journal of Wildlife Management* 86: e22167. https://doi.org/10.1002/jwmg.22167. Therefore, articles in that journal, the Wildlife Society Bulletin and Wildlife Monographs did not have the guardrails on publication ethics recommended by the Committee on Publication Ethics, which include scrutiny of potentially competing interests among authors, peer reviewers, editors, and the publisher, the Wildlife Society. Nor did the journals have guardrails for correction and retraction of misleading or fabricated science.

I asserted above that meta-analyses and systematic reviews are relatively more valuable than single studies for drawing generalizable inferences about the effectiveness of any method for preventing wolf predation on wild or domestic animals. Although the 11 studies below differ in standards of evidence, sample sizes, and inclusion criteria, one consistent conclusion emerges: without RCTs or other robust designs that control confounding variables, it is impossible to claim with confidence the effectiveness of any method. That does not mean we have zero information or knowledge, but rather that your caution should be heightened when we lack RCTs for this field of science.

Lethal management of wild wolves to protect domestic animals has only been evaluated with before-and-after comparisons without randomization (silver standard). The field should aim for the higher strength of inference provided by gold-standard randomized, controlled trials.

Effect	France	Slovenia	Michigan U.P.
Desired reduction in livestock deaths	33%	28%	25%
Undesirable increase in livestock deaths	11%	65%	75%
No effect	55%	7%	-

France (regions: Grente O. 2021. PhD thesis Montpelier U. and ONCFS q, France.
Slovenia country-wide: Krofel M, et al. 2011. Acta Silvae et Ligni **95**: 11-22. As reanalyzed for Treves et al. 2016. Front Ecol Environ **14**: 380-388.
Michigan Upper Peninsula: Santiago-Avila et al. 2018. PLoS ONE **13**: e0189729 10.1371.

*Note: Bradley et al. (2015) does not meet the criteria for reliability until they remedy irreproducible methods, a bias towards lethal control, and share their data for replication (Bradley et al. 2015. Effects of wolf removal on livestock depredation recurrence and wolf recovery in Montana, Idaho, and Wyoming. J Wildl Manage **79**: 1337–1346.)*

Moreover, van Eeden et al. 2018 in PLoS Biology showed how differently four studies regarding lethal methods published between 2016-2018 drew from the literature despite similar search criteria. "Our four reviews [6–9] jointly screened >27,000 candidate studies. The four sets of inclusion criteria differed in geographic coverage, carnivore species, and standards of evidence and research design (see S1 Table), which limited overlap in the studies that passed screening (only 19% of studies were included in two or more of the four reviews; no study was included in all four, S1 Fig). The differing inclusion criteria also meant that it was not possible to conduct a quantitative comparison (meta-analysis) combining the data from our four reviews, but we suggest that such an analysis should be conducted in the future as evidence increases. Nonetheless, our reviews came to remarkably similar conclusions, irrespective of methods, suggesting that our conclusions are robust."p.3 van Eeden et al. 2018 PLoS Biology. Because we brought together almost two dozen authors from 11 countries for van Eeden et al. 2018 in PLoS Biology, it is the leading review that drew the clearest consensus. That consensus included (a) the field needs stronger inference and (b) that lethal methods have not been studied with as high standards of inference as non-lethal methods.

Moreover, combining van Eeden et al. 2018 with more recent work indicates that several non-lethal methods are more effective in protecting domestic animals than lethal methods appear to be. Note that even though these meta-analyses do not concern only wolves, one can learn from studies of the effectiveness of interventions against other predators to draw inference about how these would work against wolves.

Among those non-lethal methods shown to be more effective and studied multiple times are fladry and livestock-guarding dogs when deployed and maintained correctly as explained in the source articles reviewed. The studies also endorse effective fencing albeit fewer RCTs have evaluated it.

Other promising methods tested by RCT only once against wolves includes range riding using low-stress livestock handling. Likewise, I recommend consideration of methods that proved effective from RCT studies with other predators, despite never having been tested on wolves, such as painted eyespots on livestock and humans assisted by deterrent noise-makers and dogs.

17. Louchouarn NX and Treves A. 2023. Low-stress livestock handling protects cattle in a five-predator habitat. PeerJ 11: e14788. http://doi.org/10.7717/peerj.14788

Recent meta-analyses of lethal methods against predators of wild ungulates suggests unpredictable outcomes. Although it did not focus on wolves, many of the included studies were of killing wolves to protect wild ungulates. The authors below review the many decades of

research on this question and note the shortage of RCTs or the poor quality of controlled studies used to address the question. Therefore, I see no scientific consensus on the effectiveness of killing wolves to protect wild ungulates. I do see consensus on a value-based issue relating to evidence; namely that the design of predator-killing programs should be treated as experiments and monitored scientifically by independent uninterested parties. A recent study in Alberta, Canada also shows that "increasing large-predator populations do not necessarily reduce hunter harvest of elk" and that sustainable hunting of elk has continued, and populations have increased with increasing large predator populations (Trump et al. 2022). Another recent study analyzing 4 decades of efforts in Alaska, US to reduce abundance of large predators, including gray wolves, brown and black bears, found: (1) no positive correlations between killing of bears and subsequent moose hunting, (2) moose hunting was negatively correlated with the prior year's wolf killing (weak relationship) and (3) no differences in mean moose hunting during periods of recent liberalized killing of predators relative to prior periods (Miller et al. 2022).

Even when interventions to protect other animals from wolves are effective, there is little consensus on how long effects persist. As the authors below have shown, virtually all studies are one grazing season or briefer. Few interventions have been studied long-term. One has to look at single studies to understand the likely short-term and long-term effects of an intervention, but then I caution the results apply only to that design and experimental set up.

23. 16. Khorozyan, I. and M. Waltert, How long do anti-predator interventions remain effective? Patterns, thresholds and uncertainty. Royal Society Open Science, 2019. 6(9). 10.1098/rsos.190826.

3. Estimating wolf abundance with methods other than validated mark-recapture methods

Recent work by Creel (2021) and Treves & Santiago-Ávila (2023) points out the many scientific shortcomings in the recent approaches taken by the states of Idaho, Montana, and Wisconsin to estimate their statewide wolf abundances. Before shortcuts can be safely taken to estimate wolf abundance accurately, precisely, reproducibly, and with sensitivity to changing conditions, the new methods should be validated by third-party, independent scientists comparing new methods to old methods. Thus far, no shortcut to mark-recapture methods has proven reliable.

4**. Killing for tolerance**

Finally, the claim that killing wolves improves public tolerance has failed multiple tests by multiple lead authors using different datasets and entirely different approaches to the question (social scientific, population ecology, wolf survival). Unfortunately, I am a co-author on almost every study, so opponents may cite non-independence of the studies. That assumes I can somehow persuade or compel other scientists to do my bidding. That is ridiculous on its face but is probably best disputed by pointing to the diversity and independence of these authors compared to the homogeneity of the opposing side.

Moreover, disputing the independence of the many studies refuting the idea that killing improves tolerance also ignores the Nordic studies that do not involve me (see below) and ignores the weakness of evidence that killing improves tolerance. The contrasting views are either not peer-reviewed, have not been replicated, have shortcomings that have been exposed in subsequent peer-reviewed work, or did not address the question.

Furthermore, some advocates for killing for tolerance have pivoted to claiming killing wolves opens a space for dialogue with a few powerful, narrow interests. Setting aside the ethics of killing wolves for that purpose, the evidence from Hogberg et al. 2015 does not support the claim because the prime target demographic group in Wisconsin (men residing in wolf range who have familiarity with hunting) had the sharpest decline in tolerance for wolves after wolf-killing was liberalized to include public hunting and trapping.

In summary

- Attitudes to wolves became more negative or did not improve when protections for wolves were reduced [1-5].
- Poaching was higher when wolf protections were reduced, measured by individual wolf survival rates [6-9].
- Poaching was higher when wolf protections were reduced, measured by wolf population dynamics [10-13]. Attempts were made to challenge the latter results, all of which failed because they lacked data to support their claims [14, 15] or had shortcomings that made them irreproducible [16-23]. Our calls for corrections of the latter studies have yielded one correction thus far [24-26]. We await further corrections and retractions.
- Poaching is the major cause of wolf mortality and it is mismeasured or under-reported by agencies because of cryptic poaching [27-29].
- Miscellaneous work on poaching and the effects of lethal management, to guide more or better enforcement and also more effective management policies: [24, 28-38].
- Note a debate in the Nordic countries remains unresolved pending sharing of all data and transparent debate about statistical methods. The Scandinavian analysis that claimed that liberalizing wolf-killing will reduce wolf-poaching has been challenged [39, 40]. Similarly, two papers by the same pair of authors studying the Finnish wolf population concluded, “We conclude that tolerance for carnivores cannot be promoted by legal hunting alone…” [41] but in 2018, they concluded, “Our results provided evidence that poaching is a matter of local intolerance toward wolves and that the problem is mainly related to wolf hunting.” [42] but suggests legal killing pre-empted illegal killing by removing wolves that would have been poached [41, 42]. Clearly, further investigation with accepted methods is warranted.
- I oppose the use of hounds in mammal hunting because the precautionary and prudent scientific study of this method has not been conducted to confirm that unlawful interactions do not occur and harm endangered species, target wildlife, by-standers, or the hounds themselves (36).

5. How research integrity influences the quality of science

Certain principles of research integrity affect the quality of science so strongly that failure to adhere to minimum standards of scientific integrity result in unreliable, irreproducible, or fabricated scientific findings. The US federal government has repeatedly tightened regulations and policies to avoid breaches of research integrity, so I will restrict myself here to point out the most common and problematic research misconduct that would render policy based on such science unsound and vulnerable to legal jeopardy.

- *Falsification, fabrication, or plagiarism is illegal for any recipient of federal monies*, which could place state and tribal wildlife agencies in legal jeopardy if they produce such work, because of federal support for fish and wildlife agencies. Financial penalties may be due upon conviction. A portion off such penalties can be won by whistle-blowers who report research misconduct (see https://www.whitehouse.gov/ostp/ for federal regulations and policies including relevant Congressional Acts).

- N*on-disclosures of potentially competing interests, whether financial or non-financial.* Authors of scientific work whose institutional affiliations are state or tribal wildlife agencies should beware of this breach because it can lead to correction or retraction of scientific articles ,following the Committee on Publication Ethics guidelines on transparent disclosures https://publicationethics.org/. Similar recommendations apply to US government agencies NAS National Academies of Sciences EM. 2017. Fostering integrity in research. Washington, DC: The National Academies Press. & Biden JR. Order PE (Ed). 2021. Memorandum on restoring trust in government through scientific integrity and evidence-based policymaking Washington, D.C.: & Treves A and Batavia C. 2021. Improved disclosures of non-financial competing interests would promote independent review. Academia Letters Article 514: 1-9.
- Other breaches of research integrity include selective citation, sloppy peer review, publishing in predatory journals that simulate peer review but publish anything if paid, and intentional use of inappropriate statistical analyses or p-hacking (De Vrieze J. 2021. Landmark research integrity survey finds questionable practices are surprisingly common. Science 7 July 2021, https://www.science.org/content/article/landmark-research-integrity-survey-finds-questionable-practices-are-surprisingly-common. Kretser et al. 2019. Scientific integrity principles and best practices: Recommendations from a scientific integrity consortium. Science and Engineering Ethics: 1–29 & Mejlgaard et al. 2020. Research integrity: Nine ways to move from talk to walk. Nature 586: 358-360. 10.1038/d41586-020-02847-8. & Nelson A and Lubchenco J. 2022. Strengthening scientific integrity. Science: 10.1126/science.abo0036. & Bohannon J. 2014. Who's afraid of peer review? Science 342: 60-65. http://www.umass.edu/preferen/You%20Must%20Read%20This/BohannonScience2013.pdf .
- A general lack of transparency, failure to share data, failure to disclose assumptions, methods, value judgments, and failure to embrace open, independent review can all affect the reliability of science. Indeed, articles published by the Wildlife Society before 2022 were published without the ethical guardrails of the Committee on Publication Ethics, COPE (Krausman PR. 2022. Improving the journal of wildlife management: A response to the perspectives of Johnson et al. (2021) and Gould et al. (2021). *The Journal of Wildlife Management* **86**: e22167. https://doi.org/10.1002/jwmg.22167), signifying that such articles should be considered less reliable until proven each article followed COPE best practices on its own. This also means the Journal of Wildlife Management is considered less reliable than journals or publishers that have been signatories to COPE for longer.
- Finally, government agencies in the USA are trustees of nature including wildlife. They are trustees for current and future generations, so their duty is to preserve first and regulate current uses second, to prevent substantial impairment of the trust assets. Catering to a subset of the public or interest groups is unlawful. Failure to regulate illegal uses or over-use is likewise unlawful.

Are wolf populations regulated by prey or are they self-regulating?

Tim Van Deelen 1/9/2023

The draft wolf plan (Plan) has a heading in section 1 entitled “Prey Regulates Wolf Populations” and ends with a sentence saying that “To date, prey abundance does not appear to be a limiting factor for wolves in Wisconsin.” This apparent contradiction requires some explanation.

Stating that “Prey Regulates Wolf Populations” is saying that there is negative density dependence in the growth rate of wolves and that the mechanism of the negative density dependence associates with declining per capita prey resources as the wolf population increases. In the literature on wolves and ungulates, limiting factors are those that influence growth whereas regulating factors are a subset of limiting factors that enforce an equilibrium (carrying capacity) through density-dependent negative feedbacks (Messier 1991, 1994).

There are two meta-analyses that attempt to describe the relationship between equilibrium wolf and prey densities. This relationship is the called the “predator numerical response.” The first analysis is in Messier (1994, Table 2) where he assembles 33 observations on coupled wolf/moose populations in North American. When plotted, this relationship is a saturating function meaning that as moose density increases, wolf density levels off (Figure 1) indicating that at high moose density something other than prey density is enforcing the equilibrium density of wolves (i.e. something else is regulating). The shape of this saturating function is known as a type 2 numerical response.

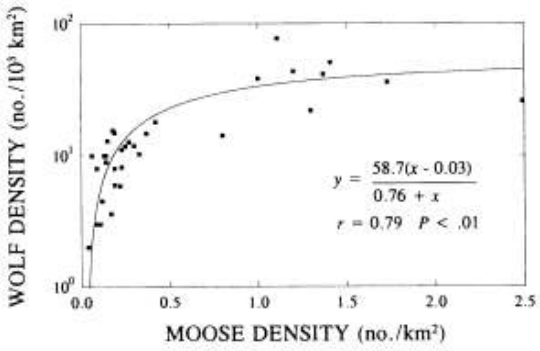

FIG. 4. The numerical response of wolves to changing moose density. Wolf density (presented on a $\log_{10}$ scale) was related to moose density with a hyperbolic, Michaelis-Menten equation.

Figure 1 Reproduction of Fig. 4. in Messier (1994) showing a type 2 numerical response.

The second meta-analysis is based on a dataset in Fuller et. Al (2003, table 6.2). This dataset contains 44 observations from studies in North America where there might be 1-6 representatives of 9 ungulate prey species ranging in size from Bison to deer (white-tailed or mule). To standardize across different prey species’ masses, they created an ungulate biomass index (BMI) which is effectively a conversion to deer-mass equivalents, hence BMI_{deer}= 1, BMI_{elk} = 3, and BMI_{moose} = 6, etc. The relationship that they show is variable, but they describe it as linear (Figure 2) indicating that equilibrium wolf densities are proportional to ungulate prey biomass expressed as deer-equivalents – a type 1 numerical response.

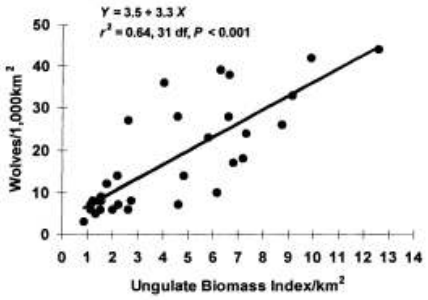

FIGURE 6.2. Relationship between ungulate biomass index and wolf density, plotted from data in table 6.2. (Adapted from Keith 1983 and Fuller 1989b.)

Figure 2 Reproduction of Figure 6.2 in Fuller et al. (2003) showing a type 1 numerical response.

Cariappa et al. (2011) re-appraised Fuller et al.'s (2003) relationship using Akaike's Information Criterion to compare type 1 and 2 models fit to the data and found that support for the two models was equivocal. When exploited or expanding wolf populations were removed (because they were non-equilibrium), type 2 models fit marginally better. Mech and Barber-Meyer (2015) added an additional high ungulate-density observation and declared that the relationship was proportional (type 1).

Some comments:

1) Mech and his colleagues argue that a type 1 numerical response demonstrates that prey numbers "regulate" wolf population growth. Strictly speaking, the type 1 numerical response only demonstrates that prey numbers limit growth. Regulation requires identification of the density-dependent feedback mechanism. A type 2 curve demonstrates that ungulate density and wolf density decouple at high ungulate density and that something else is regulating.
2) Wisconsin wolves show negative density dependence in their population biology. This is evident in the numerical and spatial patterns of growth (Van Deelen 2009, Stenglein and Van Deelen 2016) and in components of growth like survival (Cubaynes et al. 2014, O'Neil et al. 2017, Stenglein et al 2018), reproduction (Stenglein et al. 2015) and compensatory behavior in cause-specific mortalities (Stenglein et al. 2018).
3) The meta-analysis approach is relatively crude and doesn't account for different ecological contexts. A regulation-by food argument is essentially a full "bottom-up" trophic cascade argument. In fact, the strength of bottom-up forcing varies with latitude and ecosystem productivity and ungulate systems are sensitive to it (Messier 1994. Crete 1999). The curve-fitting exercises in figure 1 and 2 could be complicated by observations in systems where the real shape of the numerical response of wolves differs (e.g. differing equilibrium densities). Human influences are another important spatial factor (Stenglein et al. 2018) and could regulate apart form any prey limitation (Stenglein et al. 2015b).

Conclusions

Does prey density regulate wolf populations? Strictly speaking, probably not. Clearly, prey density limits wolf population growth, especially at low prey population density. The decoupling in the type 2 numerical response and the lack of regulatory information in the type 1 argue against regulation by prey density. Moreover, I see no evidence of strong feedback mechanism directly related to per-capita prey shortages (starvation of key age classes, nutritionally regulated reproduction). Mechanisms of regulation (e.g. the feedbacks) have more to do with variation in mortality and variation in spatial risk associated with intra-specific strife, territoriality, and human impacts (O'Neil et al 2017, Stenglein et al 2015b, 2018). In fact, density dependent mortality was independent of prey density proxies (Cubaynes et al 2014, O'Neil et al. 2017) when evaluated as a cofactor. Indeed, analysis by Y. Shen. E. Olson, and I (manuscript in prep) indicate that expansion of Wisconsin wolves occurred as an expanding wave, behind which, local density reached an equilibrium nearly immediately with growth slowing down as the wavefront reached habitat boundaries. Put another way, population growth was nearly completely related to territory occupied.

Do wolves self-regulate? Yes. Internal controls on growth are features of large mammals and apex predators and wolves are both. Review of life history theory demonstrates that increasing body size is associated with a switch from populations regulated by top-down exogenous forces to bottom up (density dependent forces) because species become too large to be safely preyed upon (Sinclair, et al.

2003). This pattern is enhanced in terrestrial carnivores who develop endogenous life history features (female territoriality, socially enforced “birth control” etc.) that enforce it (Wallach et al. 2015).

In Great Lakes wolves, the most prominent density dependent mortalities are those related to territoriality and interspecific strife interacting with human influences on the landscape (O’Neil et al. 2017, Stenglein et al. 2018). Put simply, Wisconsin wolves appear to be regulated by available high quality (minimal risky human influences) habitat through social mechanisms.

This is the day the Lord has mac

JANUARY 12, 2023

To whom it may concern,

I am writing this in regards to the DNR 2022 Draft Wolf Management Plan.

I am very opposed to creating buffer zones surrounding tribal reservations.

I would also strongly request maintaining a population goal of 350 wolves in the final plan.

Thank you for your time and cooperation in the matter.

Sincerely

Larry VanderLoo

THE WISDOM OF WOLVES

SEVERAL MONTHS AGO I TALKED TO A PERSON IN YOUR DEPT. PAUL SMITH. I ASKED WHY WOLVES ARE HUNTED. HE SAID MAINLY FOR TROPHY REASONS, SOME FOR MORAL REASONS. I FEEL DOGS, SNARES, POISON, TRAPS, BAIT SHOULD NOT BE USED IF WOLVES NEED TO BE HUNTED. NONE OF THESE METHODS ARE USED WHEN HUNTING DEER. SOME LAZY PEOPLE WILL USE DEER BAIT OR BAIT TO HUNT DEER. I TALKED TO A PERSON WHO WOULD HANG A HOOK WITH MEAT BAIT ON IT AND AND THE WOLVES WOULD JUMP UP AND BE HOOKED AND SUFFER A TERRIBLE DEATH.

I HAVE SEVERAL FRIENDS THAT FEEL THE SAME WAY.

P.S.
GLAD SOMEONE GOT RID OF FRED PREHN WHO WAS NO FRIEND OF THE WOLVES. BIG CONFLICT OF INTEREST WITH HUNTING HIS OPERATION SHOULD STICK TO TREE.

IF YOU NEED MORE FEEDBACK CALL ME

Wisconsin Wolf Management Plan Draft Review Public Comment

From: Penny Warner ([redacted]

To: dnrwildlifeswitchboard@wisconsin.gov

Date: Tuesday, February 21, 2023 at 01:07 PM CST

Hello, Please let me know that you received this email with my comments. Thank you!

1. Name: **Patricia Warner**

2. I have read **ALL** of the draft plan.

3. **I am a Wisconsin resident**

4. Overall, the plan is very comprehensive. I attended all the Wolf Management Committee planning meetings via zoom and appreciate the amount of work that went into this draft. I do however feel the committee was heavily weighted with the anti-wolf groups. These are the elements that I liked:

- The previous plan had a numerical goal of 350 wolves, and I am glad it has been removed as there has been much controversy over the intent of that number. I like the new direction of the department to use science when determining harvest numbers in future hunts. I hope science dominates planning and future quotas are set at zero as science has proven **the wolf can manage their own numbers and will not exceed the carrying capacity of the landscape they inhabit.**
- Recent surveys indicate a shift toward more acceptance of wolves in Wisconsin with wolf advocacy being in the majority of responses. Social media has promoted misconceptions concerning wolves and has encouraged hatred toward the animal that promotes cruel and inhumane practices.

    - I would like you to revisit **Product D3a and D3b on p. 131 in the proposed Wolf Management Plan** and actually **begin the work** of creating materials such as lesson plans, wolf boxes, wolf units and guest speakers, etc. that can be distributed to our public schools, clubs, church groups, scouts, etc. This would ensure that our future generations would have accurate information about wolves. Reach out to organizations such as HSUS, the Sierra Club, TWIN, TWA, etc. that could work in conjunction with DNR personnel to create a variety of materials. TWIN was very successful in the 1980's and 1990's with their development of a

variety of educational materials. Their creation of the Adopt-a-Wolf-Pack program not only **generated revenue for the DNR**, but was distributed around Wisconsin and several other states and succeeded in educating participants in wolf ecology and their role in completing a diverse and robust environment. The public's understanding of the wolf's role in our environment is particularly important now with the proliferation of CWD across our state.

5. These are the elements that I disliked:

- **Product C2H Hound hunting training should be taken out.** It is not part of the law. I own a home and 170 acres of forest land in Oneida County, and I do not want hounds harassing the wildlife on my property. Hound hunting is no better than sanctioned dog fighting **which is against the law.** Since hound owners are purposely encouraging their dogs to fight with another canid, zero compensation should be awarded to the owners of those dogs. Instead, those dog owners should be prosecuted for cruelty to animals, **which is part of the law.**
- **Ban the use of chocolate and Xylitol in baits.** This inhumane and cruel practice kills not only wolves, but dogs as well.
- **Ban hunting at night.**
- **Wolf Population Monitoring p. 64-66** As stated in your plan, radio telemetry collars on average lasted 5 ½ years. Since the implementation of the GPS collars, the life of a collar is less than a year. This is very costly for the department and suggests that the wolves are being tracked by their collars and killed by poachers. The 2020 report stated that of the 16 recovered illegally killed wolves, 13 were wearing collars. Additionally, 60 of the 76 collars were no longer sending signals. That GPS failure rate is unacceptable. **Reinstate the radio telemetry collars.** The below methods need to be continued since the department has transitioned to the new occupancy model, which is comprised of a hit-or-miss approach of guesstimating the number of wolves in our State.
    - Summer howling surveys are the only accurate way to determine if pups have been produced in any given pack. It also gives an estimate of how many wolves are present in that pack. There should be at the minimum, a summer howling sampling of known packs in Wisconsin.
    - If the department continues to rely on volunteer trackers for winter wolf counts, then the volunteers need to have training in the field with DNR personnel. An internet course cannot sufficiently train a volunteer. Over counting by inadequately trained volunteers is not helpful.

6. It is very difficult to rate this plan until it is implemented, and we see the results. I watched the NRB meetings with horror as they tried to completely eradicate the

wolf from its rightful place in the environment by overriding the DNR's recommendations during the last hunt.

7. Considering the 2022 survey and the changing attitudes towards wolves in Wisconsin, this plan should promote policy changes that will bring an end to wolf hunting and trapping in the state. In future committees, greater emphasis should placed on wolf advocacy groups to more accurately reflect the majority of the citizens in Wisconsin.

To the D N; R.

Name	Resident	Date	Time	Subject	Email Body
Tom Schwefel	Unknown	Dec142022	12:56:21	Wolf draft concerns	I have spent several hours going through the proposed new wolf draft plan. I realize you need to be thorough but a 167 glorifying wolves is a bit much. Before you think I don't support having wolves in the state, I do. 90% of what I reed before my eyes glazed over was about the poor wolf. The overall population need's to be controlled in some way. Hunting being one (noticed that some of the money funding the wolf programs are come from Pittman-Robertson fund. Which comes from sports people). One of the statements I find confusing 1)Wolves kill 15-19 deer per year. I'm assuming you are referring to each wolf? If so why not include that simple word each? If not explain further. 2) Based on the risk reward scenario wolves have evolved to become highly effective at identifying weaknesses among their prey. I don't doubt any predator doesn't go after weak or sick animals. It's obviously easier to run down. What do they do when they don't find sick or weak prey? Wolves are very intelligent pack animals. They more than likely will go after whatever is available sick or healthy. Your comments make it sound like they only go after sick animals. I'm not a wolf expert. I am willing to bet a pack of wolves can run down a full grown elk or deer in snow. Let's face it the elk program cost millions of dollars. The state has struggled to grow the herd. Having wolf packs that continue to grow in a area that has a elk herd is wasting money. One of the charts showed no elk killed in 2018 by wolves. I find this absolutely impossible. What I do find interesting is how few elk are confirmed killed by wolves. For that matter deer as well. What are the wolves eating? 3) One of the statement's claimed that wolves account for 34% of elk mortality and the elk herd is growing at 10%. Sounds like the elk herd is on the loosing end. How many wolves do you estimate to be in the Clam lake herd area? 4)Estimates of 292 wolf packs(this is your number). Average of 4 wolves per pack (again your number). 292x4=1168 wolves in the state as of 2022? Is this correct? The DNR was in a huge panic when hunter's (Again who are paying for part of this program) shot 219 wolves in 3 or4 days. Might be off by a day or 3. This was in 2021. The sky didn't fall, the sun came up and low and behold we still have 1168 wolves based on your numbers. 5) There is a percentage of human mortality for wolves that you give. 29%-35% that is acceptable without causing concern for wolf numbers. This would for a overall human mortality number of339-409 wolves. Am I correct? 6) Input from the tribes. The tribes do not have to hunt/kill any thing they don't want to. Any wildlife on the reservation that they want to protect should be up to them. Outside the reservation is considered differently and should be managed accordingly. Not just with one groups input. If the state just decided it's going expand management of some species because of special interest groups is just plain wrong. Again you get money from Pittman-Robertson fund. Needless to say I couldn't finish going up through the overly long one sided draft plan. If I found time in my busy schedule I will continue to look at the draft, so this may not be the last you hear from me. Not that I expect to have any input into the final draft. Unfortunately I didn't receive a questionnaire so this is the only input I will be able to contribute. It amaze me how much trouble the wolves have caused. To bad there isn't give and take on both side's. Thanks Tom Schwefel
Mike Kohl	Y	Dec142022	16:51:00	wolf	get the politics out of this . you are not listening to the people of WI.. we vote on something and you do what you see fit. listen to the committees . mike kohl president of outagamie conservation club. wiocc.com thank you
Kevin Feind	Y	Dec142022	20:47:34	Wolf Study Comments	Randy, I have read the draft plan twice. As cited, there has been a significant amount of polarizing views on the wolf in Wisconsin. I feel without some safety checks in the population estimates based on track surveys, there is a risk of bias as to counts. With public involvement in counting, I feel there is quite a risk at high or low track counts due to person opinion (people lie). I question the ability of doing track counts on private lands. Accessibility must limit volunteers' effectiveness. I'm concerned that the area of western Wisconsin that appears to be labeled as outside of wolf range. To the commoner, that sounds as if no wolves exist there. I don't see that as possible. I don't see documentation of wolf population estimates on tribal reservation lands. Obviously, that number needs to be established, if it hasn't been, and added to the state population count if it hasn't been. I've had a 25 year career with the DNR, and know how the Department historically struggles to communicate with the public. This poor communication has resulted in distrust, frustration, and anger. Procedures need to be established to help in communication. This should include personnel that actually know something about wildlife, and a regional media representative should be considered. The woman in the deep south has done a poor job due to her "big city" unconnected background. Regaining trust will be an uphill road. I was very involved in the reintroduction of wild turkeys in northern Wisconsin. In the turkey program, we also had to overcome what was once considered unfavorable habitat. Today, turkeys have surprised even the most optimistic, with how they've done in the far north. Now, we see that "unfavorable habitat" classification to areas that should have wolves, such as western Chippewa County to the state line. With this classification, I fear track surveys are either limited or not done at all. This again leaves a huge hole in the overall state population estimate. Thanks for your time. Kevin Feind Solon Springs, WI
David Russell	Unknown	Dec152022	3:40:29	Wolf management plan draft	It does not need a hunting traping season as wolves never need to be killed and there aren't enough left to sustain a season. Deer over populate as do many other hunted wildlife but wolves are not, please leave then alone.
Ieva Zariņa	Unknown	Dec162022	6:00:23	Comment on Wolf Management Plan	Dear Sir or Madam, I would like to comment on the wolf management plan and specifically, I would like to oppose wolf hunt which has been included in the draft despite the fact that it is not legally admissible in accordance with the federal law. There are also ethical and practical reasons why hunting wolves is wrong and counterproductive. 1. Wolves are powerful agents that can assist in species regulation, recovery and the fight against the climate change. 2. Killing wolves actually increases the risk of wolf-livestock conflicts; 3. Wolves, as apex predators, are largely self-regulatory and hunting/culling can, in fact, increase wolf density and cause the related problems of over-exploitation and conflict; 3. Wolves are highly sentient, form deep attachments and they are truly devoted to their families and capable of grief which is why it is wrong to estimate their demographics as mere numbers just like it would be wrong to kill people who are in excess in some region. 1. Wolves as powerful ecosystem health agents. Wolves are a keystone species and also, an umbrella species. It means that many other species depend on wolves and by protecting wolves, you also protect these other species. While it is more clearly conceivable how wolves might affect their prey species or scavengers, wolves actually bear benefits to songbirds, amphibians, reptiles, plants and even the quality of riparian systems. You can read more about it here<https://secure-web.cisco.com/1gemQeppp1sZ36-H0LKMK6OL-yNVSVs5-I6-lw6spMUO-wKbhg1gjGnBGgpbLNsz9SF8pJNTigp-8LV9auX3sgByVp-xfy7z9qeeiz3od9W0_iaStbIgqllKmqKhasLJR78Klm2GP9lIuJmyD0mcUz6ShCcBfEaAOg2WzjFhXEKGDBep3SLmun0KYJv7wrAYvQZVeDxN0XNyW2SuCYnPfuU-JLFWssQ-1auu8uBgvrOJOVR1pCtrh5GNV7hAJZ0mIV4_lS3vcCA5ipTppoFLWF7v4YW20JQMttRON4RtmPz3uH-zT1txwi7aVgxa4lTyWlbAHDStUMoq-EKhTTEfKZA/https%3A%2F%2Fwww.livingwithwolves.org%2Fabout-wolves%2Fwhy-wolves-matter%2F>. In fact, wolves are so powerful that even in small numbers, they bring large benefits that manifest themselves in the entire ecosystem and that is why some of your best scientists have recommended rewilding and nature restoration projects that rely on two key species - wolf and beaver (you can find the link to the publication in this document<https://docs.google.com/document/d/1XGovY_ZY23RMBHAtL4c2jSzXEaFX6JaO/edit?usp=sharing&ouid=106495592074605043817&rtpof=true&sd=true> where I have listed wolf-related scientific publications any wolf management expert should have read - I have also added brief summaries of the key points). When it comes to their prey species, wolves can

Name	Resident	Date	Time	Subject	Email Body
					ensure long-term health through removal of sick individuals but also through genetic selection (removal of breeders with poor genetics who would pass on the disease-gene to their offspring). Wolves can help in limiting the spread and prevalence of such diseases as chronic wasting disease, brainworm, tuberculosis, osteoarthritis among others. While we often consider wolves as 'killers' and 'harbingers of death', it is a wrong view - wolves kill only as much as it is necessary in order to keep the total of death to minimum. This means that, under normal circumstances, by the act of killing (or even simply by residing in an area), wolves will reduce the total number of deaths through decreasing the rates of disease or overpopulation-related mortality in ungulate communities. Such mechanisms do not necessarily need to rely on killing. Where wolves live, ungulates tend to gather in smaller groups and to change their movements which can also curb the infection rates by limiting social group contact (just like during Covid, we are advised to keep distance from one another and to avoid large social gatherings). Unexpectedly, wolves can also reduce, for example, road traffic related mortality. A study in Wisconsin (also included in the links in the aforementioned document) shows that wolf presence changes deer behavior reducing deer-vehicle collisions by as much as 24% and consequently, saving $48 million. The same study states that wolf-caused livestock loss in Wisconsin can reach $174'000 annually. Also, it is worth considering how much wolves 'earn you' through tourism, science and education opportunities and through the reduced disease rates or even by improving the quality of water. Wolves are great allies and helpers and the species that scavenge on their kills are often endangered (birds of prey, wolverines, pine martens etc.). Another research shows that with climate change, scavenging species might be at risk through the reduced late winter mortality which can be detrimental on a population demographics level because late winter carcasses offer important resources building up the animals' fitness for the reproductive season. Breeding success depends on foraging success and species like wolves can deliver a more equally distributed abundance of carrion throughout the winter period. These are just a few examples on why wolves are important and why wolves are not a threat to us but some of our most powerful allies. All of these services, however, depend not just on wolf numbers but also on the stability of their social groups and local populations (which is why a declining population suffering hunting pressure is not desirable) - if wolf packs are unstable and the demographics are fluctuating, wolves will not be able to carry out the same activities with the same consequences. For example, if wolf pack is disrupted due to loss of members (breeders or old, experienced wolves), wolves will not be able to hunt successfully and they might begin relying on other food sources that are not their main prey. Such food sources could even include livestock (lone wolves and small packs that cannot take down large, wild prey or do not have the accumulated knowledge of their home territory, will be forced to roam and get whatever food they can - an easier prey). 2. As I mentioned before, wolf packs that are disrupted can cause greater risk to livestock farming. Usually, wolves do not select attacking livestock, especially, if livestock is found in areas close to human settlements or protected by fencing, guardian dogs, range riders etc. Wolf main prey is large ungulates (elk, moose, white-tailed deer etc.). However, wolves are opportunistic predators. If wolves are travelling alone (dispersing wolves, wolves who have lost their pack etc.) or in small groups, they will not be able to take down large savvy wild prey and they will be unfamiliar with the surroundings (difficulty to locate prey). Under such circumstances, wolves are likelier to attack livestock if they come across it. Also, in unstable, disrupted wolf populations, there are vacancies filled by newly arriving wolves who are unfamiliar with the territory and who have not yet formed a pack - these situations cause greater risk to livestock. Similarly, hunting has the tendency to reduce the number of old wolves in the population. Old wolves have the knowledge of the prey and territory as well as of the defense and territory maintenance. Without this knowledge, young wolves will not carry out the same behaviours as wild wolves under natural conditions. (Moreover, wolf breeding success actually peaks at the age of 2-3 years after which it declines. Thus, removal of older wolves can increase local wolf density because only younger breeders are left who produce more pups.) That is why stable local populations are beneficial over declining, fluctuating populations and disrupted packs. In the list of publications you will see that wolf hunting can increase the risk of attacks on livestock in the following year by 4% in cattle and by 5-6% in sheep (risk rate increases with each wolf killed). Additionally, if one ranch 'protects' itself against wolves by trapping/hunting, this causes a displacement of the problem and neighbouring ranches in other regions suffer greater depredation risk. Preventive methods<https://secure-web.cisco.com/1qmMzxxiNFFgVbV83rn5R8HAcCBIBnUJ9ihWoTXEcJld4apOqk3A-wzPUN9j08iTKmuFBfKNU1yybgNcn-GOm7FL3Q1zdyppR-OxLsBSCZN9xmlVJuE1F1LV8RkQq0nisMfFdAIODx9ixe9weA8w1ZF-fTmqMR8ZHeAUgSffEDWZqwXTBTXIm49j5pd5ti1ouGW55istUUisHtKncWgiY_0U5QnpFTxZ-WjWOm40JryFxZzRtf1gsHuzNfQvMnT6AvoiN3YX7UasOelOPHhtz0Obq0Aqn3nCAy7ab6UiP5X6YRgWtUa5z6TXzm4X2ktPz4cxlL2NH4kXA7DKM7gRWYw/https%3A%2F%2Fwww.coyotewatchcanada.com%2Ffiles%2FWolfAwarenessRanchersGuide2ndEd..pdf> (such as electric fences, guardian dogs, guardian donkeys, fladry, carcass removal etc.) are far more effective (at least 95% efficiency rating) and do not pose the aforementioned risks. Also, people tend to exaggerate the actual conflict rates and wolves kill, for example, less than 0.04 sheep per year in the U.S. of the entire sheep stock while large percentages of livestock are lost to disease, bad weather, calving complications, poisonous plants etc. More livestock units are stolen by humans than killed by wolves. More sheep are killed by dogs than by wolves. Furthermore, research in Europe and USA shows that there are no problem wolves. In places where habitat will be too fragmented, wild ungulate availability too low and livestock will be accessible, wolves will be pushed to attack livestock. Those are 'problem places' that create 'problem wolves' and removal of 'problem wolves' will not resolve the issue of the 'problem place'. Any wolf that will end up in the 'problem site', will, once again, become a 'problem wolf'. Therefore, the issue of the site specifics (why wolves attack livestock instead of hunting down wild prey and how this can be prevented through fencing, guardian dogs etc.) has to be solved in order to stop the attacks. Culling of the wolves will be inefficient because after these wolves are gone, other wolves will move into the area and the issue will be renewed. 3. Most life forms in nature are regulated by either bottom-up or top-down effects. Bottom-up effects include the population's dependency on food resources (a reduction in food availability can lower population numbers and/or demographic rates). Top-down effects are usually predator-induced - it is how predator species regulate prey species numbers and other demographic parameters. (Other agents of control are for example, disease-causing bacteria, viruses, environmental changes or extremes etc.) Large predators like wolves are regulated by their prey species but they do not have a top-down regulating agent because they are not anybody's prey. Wolves can sometimes be killed by other predators due to competition but such killings do not form a regulating mechanism. It is therefore thought that wolves might need external regulation. But, like most large predators (based on body mass), in normal circumstances (meaning that the ecosystem is not severely degraded or subject to other dramatic deviations from what is natural, or impacted by humans through anthropogenic food resource availability in garbage dumps etc.) - wolves regulate their own numbers through biological and social mechanisms. Hunting and culling can, in fact, reduce the efficiency of self-regulating populations and become counter-effective. Biological mechanisms through which large predators (including wolves) self-regulate depend on smaller litter size, giving birth only once per year (or like bears, only once every 1 - 3 years). Large predators tend to rather invest in fewer offspring (unlike many other species who rely on the quantity of offspring attempting to compensate potential loss via greater numbers of children). Also, due to their larger size, large predators need to maintain bigger territories (in order to satisfy their metabolic needs by including the optimal number of ungulates over a range of habitats). Wolves defend their territories which is why only one wolf family (pack) will occupy their large territory. This reduces the number of wolves per square miles and wolves will keep their large territories pushing out other wolves (a partly social mechanism). This sets a limit on how many wolves can actually live in a specific area

Name	Resident	Date	Time	Subject	Email Body
					and wolves themselves sustain that limit. In places where wolves do not live, often smaller predators thrive who have larger litters and who have smaller territories. Thus, without wolves you can end up with more predators per area (a higher predatory density). Equally, in places where the local population is constantly disrupted through hunting, the territories will fluctuate and wolves will need to start off with smaller packs that cannot defend large enough territories. The number of wolf packs can increase and these packs would be initially smaller but they would nevertheless produce pups to establish their own social group. Such constant disruptions can thus lead to smaller packs, smaller territories, and more wolves per area (higher wolf densities). Another self-regulating mechanism is carried out through breeding suppression and alloparenting. It might sound complicated but you already know what it means - it means that in wolf packs, usually, only the breeding pair will produce pups and other pack members will assist in raising the pups of the breeding pair. Thus you get a pack unit in which not all wolves who are capable of breeding, produce pups. The wolf density per area is thereby even further reduced. When wolves are lethally removed, once again, new packs are formed and many wolves who did not have a breeding opportunity, come by one. While it might sound nice, it can be detrimental to the resource stocks because too many breeders per area can produce too many pups and the demand for resources can exceed the capacity of the local ecosystem. Additionally, in such affected populations, small packs might try to increase their numbers in order to have enough providers and defenders in their pack and to reach a normal, average pack size. Thus, more wolves can be allowed to breed also within the pack. Because in hunted populations, vacancies are often filled by strangers (migrating wolves), breeding rates can increase due to the increased encounter rates with unrelated individuals. Wolves tend to avoid inbreeding (breeding with close relatives). In stable populations it is harder to meet unrelated individuals and thereby, to get a breeding chance. In disrupted populations, wolves roam more freely and the chance to meet an unrelated wolf is greater. You can see now that, oddly, removing wolves can actually increase local wolf density and even wolf numbers. The more frequent the disturbance, the lower the likelihood that wolves will reach the self-regulating capacity by forming large enough packs that can maintain large enough territories and hunt down large enough prey and where breeding opportunities are essentially limited at 2 wolves (a breeding pair) per 100 - 6000 km2 (wolf territory size). 4. Finally, there are ethical considerations. If you visit the Wolf Science Centre (Austria) website<https://secure-web.cisco.com/1ic-KEd81ihh1kAm1DgnZ0nG6Xi3HO7tCRvmn8RI3MX_t5bVMvOgrhTV3gRHMEqog2H806er4muKPWRrcrCgWotTx65ISYonlk_H-Sl6MiRlnBC_6XNHUgOeqIZ9oVsI2pzFUL8-rCnhlmjaGpUDx3g6CAcKbmxIAOkyoE4A4lZDleLXixF8IEGsYyfb5d_wmVECVLvte5rFtaophGk4tNt5Y40vj5LQNHL2_oQAzhWG1_Zyyc3FEqyIJg6_Z8J3U-L0SAiODo-sX4JMmlxU2mkTpbaLgqiY68S4InCgTigL9Da8l9_tU4_Hah0EtFzyYgxCis5Y-9lUXqTpWV7yHhA/https%3A%2F%2Fwww.wolfscience.at%2Fen%2Fwsc-research%2F>, you will see an abundance of scientific publications dedicated to wolf sentience, prosociality, affiliative relationships, intelligence etc. You will see that wolves are not different from dogs but when it comes to social bonds and cooperation (even with humans), or other aspects of intelligence, wolves frequently surpass dogs. Their research has actually led to discoveries that suggest - humans are not responsible for the cooperative, friendly nature of our companions, the dogs. These traits are inherited from their wild ancestors and humans have only redirected them so that dogs form the same attachments that wolves do - but with us, humans. Whatever you think or feel about dogs, you should be thinking and feeling about wolves. Dogs, too, kill sheep. Would you feel it a justified decision to kill stray dogs randomly because one poor animal killed somebody's sheep? Or would you rather try to see the bigger picture inclined to justify the dog and to see how it is our responsibility, as well? We tend to think more highly of dogs because their affections and cooperation are directed at us but wolves possess the same traits, only they direct them at one another within their social groups. We also tend to think of wolves as killers but it is very likely that wolves actually kill fewer animals than dogs do (than we do) if we realize that our meat consumpion is a paid-killing. Wolves only feed 2 - 3 times per week and it is possible that their consumption rates are lower than ours and those of dogs'. They provide for themselves instead of paying someone to butcher livestock. Through their activities, health and balance is brought to their prey communities and it is how they earn their share. From the ethical perspective, studies have demonstrated the strong bonds that wolves develop for one another. For example, wolves tend to howl more frequently when someone whom they have bonded with is gone for a period of time (as compared to when a dominant wolf is gone for a while). This means that wolves howl out of sadness and longing for their missing 'buddy', not merely out of fear and anxiety that is attributed to situations when a leader, an authority, the main provider has disappeared. Wolves are extremely prosocial. For example, in order to rescue endangered species, sometimes wolf pups are added to wild wolf mothers' dens alongside the mothers' own offspring (of the same age). What is the success rate of such adoptions? 100%. Wolves raise these young as their own. Do we have a society in which adoption is a 100% successful? Wolves even adopt pups of their 'enemies'. Male wolves who take over the breeder's role in a pack by killing or chasing off the former breeding male, extend their protection and provision over the former male's offspring. Many times you can observe interactions between wolf siblings<https://www.youtube.com/watch?v=T4iPx3JrTvc> where you would be surprised to learn that the patience and caring that you are witnessing is not between a mother and her pup but rather between the big sister and her younger sibling etc. If you have younger siblings, you will know not to take this level of tolerance for granted :) Many books have been written by wolf scientists and many movies have been made and in those, you can encounter stories of valour and loyalty and grief over loss of loved ones and acceptance, forgiveness, bravery. For example, there is a story of a wolf family which trespassed in another wolf pack's territory and got caught. The family consisted of a pregnant mother, a father and four pups who were too young to fight the much larger pack who now sought to defend their territory (and you will remember why it is important for wolves to do so - if they do not defend their territories, it can put the whole ecosystem at risk of depletion). Thus, the male wolf father is the only one who can protect his family. And despite the odds of a far greater number of strange wolves approaching, he turns around to stand against them and to fight to his death because this could give a chance for his pregnant mate and children to escape. He confuses the attackers by running through their lines but his children cannot watch his father fighting on his own. His children are too young and too small to fight but they can run. So one of them runs out in the open thus enticing some of the attackers to follow. Two more of his siblings join in and do the same until their father is left to stand against four adult wolves. The young wolves and their mother escape and their father manages to fight off the four wolves but he is very injured and he is close to death. Later, his family howls to try to call him back and to hear his voice and to know what is happening but he does not answer. On the following day, his pregnant mate risks her life wandering back into the rivaling pack's territory to track down the male. She finds him and she does not leave his side for many hours until it becomes too dangerous for her to stay (if she dies, her unborn pups die, and very likely, so do her last spring's children because they are not yet big enough to provide for themselves on their own). Soon after she leaves, her mate dies having succumbed to the injuries he received while protecting his family. She had had the opportunity to say her goodby and he has seen that his sacrifice resulted in the survival of his family. He dies a successful protector. This is just one of such stories of sacrifice and loyalty. There are other stories where packs appear to grieve their lost mates. Scientists have found wolf skulls that suggest - wolves care for their injured pack members. The fractured jaw evidences that the wolf has received a blow (by an ungulate hoof) rendering him unable to hunt and to feed properly. But the wolf has survived years after his injury until dying of other causes. Which means that his pack provided for him and maybe even regurgitated food for him until he recovered. Wolves with mange are not banned from their packs and instead, they live largely 'free-riding' and benefiting from other pack mates' greater effort in provisioning. Wolves with mange are more

Name	Resident	Date	Time	Subject	Email Body
					likely to recover in bigger packs and these packs provide them what is essentially healthcare and social care due to partial disability. Such insight suggests that it is wrong for us to treat wolves as 'management units', numbers that can be added up or retracted to our convenience. So what are we to do? We should allow for stable populations to form. We should introduce preventive, non-lethal coexistence measures<https://secure-web.cisco.com/1qmMzxxiNFFgVbV83rn5R8HAcCBIBnUJ9ihWoTXEcJld4apOqk3A-wzPUN9j08iTKmuFBfKNU1yybgNcn-GOm7FL3Q1zdyppR-OxLsBSCZN9xmlVJuE1F1LV8RkQq0nisMfFdAIODx9ixe9weA8w1ZF-fTmqMR8ZHeAUgSffEDWZqwXTBTXIm49j5pd5ti1ouGW55istUUisHtKncWgiY_0U5QnpFTxZ-WjWOm40JryFxZzRtf1gsHuzNfQvMnT6AvoiN3YX7UasOelOPHhtz0Obq0Aqn3nCAy7ab6UiP5X6YRgWtUa5z6TXzm4X2ktPz4cxlL2NH4kXA7DKM7gRWYw/https%3A%2F%2Fwww.coyotewatchcanada.com%2Ffiles%2FWolfAwarenessRanchersGuide2ndEd..pdf>. We should value wolves and exert the policy of true accountancy where we stop viewing wolves as a cause of economic loss where the loss is in fact a tiny fraction of the profit the wolves bring us. We should spread the word and educate the public and disallow lies to be circulated in the media. Public education has been proven to increase tolerance toward wolves. After what you have learned, do you not regard wolves differently already? Research in Germany shows that people who know more about wolves, also have better experiences with wolves and attest to greater tolerance levels - they do not mind wolves living ca. 30 - 35 km from their homes. School trips can be arranged to visit the Europe's wolf conservation and science centres which would especially benefit children from rural communities by forming their founded opinions early on and teaching them the basic principles of coexistence without which we have no future. You can familiarize yourself with specific publications here<https://docs.google.com/document/d/1XGovY_ZY23RMBHAtL4c2jSzXEaFX6JaO/edit?usp=share_link&ouid=106495592074605043817&rtpof=true&sd=true> (it is a list I have compiled including brief summaries of key points). I believe that any wolf population manager should be informed on these findings. Thank you for considering my message. I hope you make the right decisions. Sincerely, Ieva Zarinja
james federman	Unknown	Dec182022	21:07:31	Wolf population	I am in favor of fewer wolves, higher hunting quotas .
Margaret Melville	Y	Jan12023	8:39:07	Wolf Hunt	The last wolf hunt was a debacle for the State of Wisconsin. That hunters outside of Wisconsin could sue to kill wolves was an abomination and embarrassment. The DNR needs to be vigilant in protecting wolves and their habitats. They are an integral part of the ecosystem. Margaret Melville Cedarburg WI
jane woosencraft	Y	Jan12023	11:10:13	Wolves	I tried multiple times to enter my email in order to get a code to enable me to comment on the wolf plan, but it won't work. Hopefully the new plan will not allow the wolf kill quota to be exceeded by 83%. Thank you. Jane Woosencraft Green Bay, Wi
Tom Murn	Y	Jan12023	13:14:08	wolf management in WI	DNR re recent proposal for wolf pack number adjustments in WI -- the figure I will keep referring to is 1 wolf pack per 50 sq mi in old growth forest. I assume that would be the target for management of this resource. the emphasis should be on restoration of old growth forest over larger continuous areas while continuing to limit wolf interactions with the public and the public's assets such as livestock. Thomas Murn Newark WI 53511
David Waggoner	N	Jan12023	13:19:56	Wolves	I live in California and travel every summer to fish trout in Burnett,Washburn, and Polk counties. I place a high value on seeing wildlife as I fish the streams. Frequently I see deer. And occasionally I see bears, beaver, otters, mink, turkeys, fishers, turtles, and many species of birds. Once in 50 years I had a wolf trot by, following a deer, and 5 minutes later came by again. He saw me and paid me no attention. That was a thrill of a lifetime. Count me as a tourist that places a high value on being able to see wolves. Dave waggoner Newport Beach ca [redacted]
Tammy Vignali	Unknown	Jan12023	13:48:56	Wolf Management	To whom it may concern, Having a wolf hunt is disgusting and completely irresponsible for an endangered species. It also shows Rich boys with guns Trumps Our environment. The only thing that should matter is what is best for the wolves and our environment. Look how letting rich and greedy people do what they want to Our environment has gotten this country. Let's start doing what's Right. Extremely disappointed in Wisconsin, Tammy Vignali
	Y	Jan22023	11:03:13	wolf management plan comments	Hi, I have 200 acres of land near HWY k in oneida county, we manage it for wild life and timber, have food plots and we do very selective harvesting of the resources, we almost treat it as a preserve. in resent years there has been a great increase in the wolf population and severely depressed deer numbers, we have 9 cams out all year, this year we had 15 wolfs at one time on a cam, I know this seems unlikely but have it on cams, ususally we see 3 or 4 at a time, my neighbor has horses and they get terrified by them and one was attacked he said, neighbors are afraid to let their dogs out, the wolfs are becoming much more bold, one followed me for a short while when cross country skiing , the local dnr wants wolf management and is frustrated there is none now, I thing this is a politcal hot potato now, please use common sense on how to manage the population, Thanks,
Mary Shabbott	Unknown	Jan22023	14:15:30	Comment on the wolf plan	If any type of wildlife/management plan hopes to follow science with the animals being the priority, NO type of hunting will be included. You can not boast a new, updated wolf plan that protects this keystone species and include hunting. Nothing good ever comes from hunting these animals. They take care of their own population. They self-regulate and do need your interference. Leave them alone. Provide protections for these animals and stop coddling a small minority that only wants a trophy hunt. Mary Shabbott
Jacob Lewandowski	Unknown	Jan22023	17:18:58	Wolf management plan comments	To whom it concerns, I am writing in regarding the wold management plan. I believe we should look at regulating numbers of wolfs with the means of legal hunting/trapping practices. This is better than using tax dollars for federal wildlife hunters/trappers. I also believe we need numbers that mirror the 350 originally decided on or at a number very similar. I believe we should go with a hard set number. We also need to diminish the reservation system from the plan where small sub zones are created. This adds more confusion. It also is not right that they have say over an animal which is not the reservations property, but rather the state when it steps its foot off the the reservation property. Thanks, Jacob Lewandowski
Roy Eliason	Unknown	Jan32023	8:47:17	FW: DNR Website Information Request: Endangered Species and Natural Communities	Wolf control is an issue in many countries. Instead of culling them why not tranquilize them in the field and spay and neuter them there?
Chad Brown	Y	Jan42023	11:35:26	Wolf Plan	Reduce the wolf population! There is no way that the population should have been allowed to get this big and hunters demand to be allowed to hunt wolves, and thereby protecting the big game species that THEY PAY to harvest. Thanks. Chad Brown [redacted] Oconomowoc WI 53066

Name	Resident	Date	Time	Subject	Email Body
Pat Haimerl	Unknown	Jan42023	11:50:46	Wolves destiny	My comment is to keep the pack and let it grow... The wolf shows us it belongs to something greater than itself. Please share with the advisory board. Thank you Pat
Jason Starke	Y	Jan42023	12:15:12	Wolf comments	Hello DNR representative, My comments are written as a tax payer of our State and not as a representative of our State. I do not feel that wolves should be allowed in the wild as they present a danger to children that play in or near a wooded area. -At the very least the person that witnesses a wolf stocking a child should be able to shoot it on site without fear of the DNR. -We should have at least two separate seasons that should be limited to what the Federal Government recommends for the total estimated population to be a viable hunt. - Again these are my comments as a tax payer. Thanks
Jane Lochowicz	Unknown	Jan42023	16:34:09	FW: DNR Website Information Request: Endangered Species and Natural Communities	Hi: This is in reference to the wolf hunts in our state. My opinion is the State of Wisconsin has spent my hard earned taxes on getting the wolves back into the state as they killed into extinction in the last century. Now you want hunters to again hunt them to extinction. Why? You can't eat their meat like deer or turkeys nor do they use their hides for clothing or rugs. So why bother killing them. I am not in favor of killing them for any reason. If there gets to be too many of them, then the DNR can trap them in cages and send to Alaska or ask Canada if they won't take some of them. Wolves are too much like our pet dogs and they don't kill dogs do they? Thank you. Jane Lochowicz
Phil Kendall	Unknown	Jan42023	16:50:13	Horrendous wolf plan...	Your agency is hated for reasons like this! You need a number!! How many wolves are going to be allowed in the state?? If I answered the waterfowl surveys each year without giving numbers how much help is that? How many ducks did you shoot last year? Several. Is that a good answer. Two can play that game. Quit putting politics in the DNR, you are a useless Madison liberal agency and that is no secret. Now get a real [redacted] plan with a number and release it to those of us that pay your wage. Aka the TAXPAYER...You guys are a pathetic joke!! Phil K.
Ken Hanson	Unknown	Jan42023	18:22:04	Wolf Regulations	I am in favor of a severe reduction in the State wide wolf packs..I know the liberal judges and I'm a liberal won't have the courage to conduct controlled hunts to put the population back in line with what was originally planned. The population has EXPlODED! Our Native American brothers have not lived up to their harvest quotas and with no quotas in place the population is out of control.It's time to rethink the wolf carrying capacity numbers and quickly restore that number back to what was originally established.Thank You. Ken Hanson.
Ron Van Straten	Unknown	Jan42023	19:29:07	Comments on draft Wolf Plan	DNR Staff, I have read the draft wolf management plan and have the following comments: #1 The plan needs to have a numeric goal for wolf numbers. Without this metric the plan is useless. #2 I agree completely with the 32 comments and objections brought forth by the Wisconsin Wildlife Federation Thank you for your time and effort. Ron Van Straten [redacted] [redacted]
Drew Charpentier	Unknown	Jan52023	5:01:44	Wolf Plan	Good morning! I agree with the thousands of deer hunters in northern , the WWF, and CC. Your Wolf Management Plan is full of holes, and is biased towards wolf advocate groups, and once again driven by $$ not management. There needs to be an annual quota of at least 350 animals if the deer population will ever start to rebound in northern Wisconsin!! You cannot have a balance without an annual harvest to control a population increase of any species? I agree with Dean Bortz(every word) from the latest issue of Wisconsin Outdoor News, and the members of the WWF Board refuting your proposed Wolf Plan!!! You need a numeric population goal, and an annual harvest to maintain that goal. The DNR is already behind 2 years in managing the wolf population! Your job is to manage the growing wolf population. You are failing. Like I said before, myself and many of my fellow hunters in northern Wisconsin concerned about our decimated deer population will not wait for the DNR/Feds to make up their minds about a Wolf Management Plan. We are taking matters into our own hands!! By stalling and not having the fortitude to make sound management decisions, the DNR(you), are risking losing millions of dollars generated by Wisconsin deer hunters! And as mentioned by Dean Bortz in WON and the WWF Board, your trying to sweep the dog depredation issue under the rug. Dogs are not being depredated just in large tracks of public land! I have a Wildlife Management degree from UW Stevens Point. I went to school with Jeff Pritzl. In fact we graduated together. Jeff and I were taught by the likes of Christine Thomas, Dean Trainer, and Dr. Payne. Your proposed Wolf Management Plan would get an F from those above. Key principles of a sound Wildlife management plan are population dynamics, population goals and carrying capacity, and population controls and harvest structure. Stop appealing to special interest groups, $$$, and the DNR's agenda, and start doing your job! The future of Wisconsin's deer herd, and our declining deer hunting public is in your hands!!!! Drew Charpentier PS This letter is circulating
John O'Leary	Unknown	Jan52023	8:21:05	Wolves	The DNR needs to reduce the wolf population. They have decimated deer populations in certain areas. In my opinion the only good wolf is a dead wolf
Phillip Parsche	Unknown	Jan52023	17:58:21	New Wolf Plan	Good afternoon, It seems to me that as the result of outside groups or jurisdictions, that the DNR new plan reflects a concern from these groups and pulled in their horns from the original plan. I believe the original plan should serve as a model for future plan development. Minimum and maximum numbers need to be set. The original numbers of and control of a herd of 350 clearly understated the ability of the wolf to propagate freely. Actually, zones of carrying capacity have been reduced. More concrete, less forage (a clear loss of grouse, I.E.). Maximum herd size of 750 at which point the management to 500 is put in effect. Wisconsinites must care for our natural resources. Not some wolf hugger that lives on the 80th floor in New York city. Phil Parsche [redacted]
William Draves	Y	Jan52023	20:51:11	Protect and grow wolf packs	Thank you for the opportunity to comment on the DNR wolf plan. Wolves are part of our environment, diversity and biology supporting human life. With the crisis in climate change a threat to our way of life, We need to support wildlife diversity as God intended when s/he created us and them. -Do not allow local entities to decide on 'kill' numbers. -Set a statewide goal of 1,0000 and get there. -Create a fund for farmers and others who suffer livestock or pet losses. I've seen several wolves in the wild. They are beautiful and never came close to harming me, or anyone. No one in the state's history has been killed by a wolf. [redacted] Presque Isle, WI 54557
Gerald Francis	Unknown	Jan62023	16:45:08	wolves	I am taking the time to write to ask the DNR to start respecting Wisconsin sportsmen and start maintaining the wolf population that was originally planned in our state, which is 350 animals. The WWF is right on track with their recommendations and that should be acted on instead of kicking the can like the DNR has for the past how many years now. I have been an avid Wisconsin outdoorsman my whole life and have spent many years in the northern part of the state. I am quite frankly disgusted with the number of wolves that I see throughout my vacation time to the woods. I went from seeing one track a year to multiple wolves per camera throughout the year. I, and all Wisconsin outdoorsman, are asking you to start doing your jobs and working at getting the wolves delisted and back in the state's control. Not only are outdoorsman sick of this, but farmers that are losing livestock and in turn their income to survive, are as well. Respectfully Gerald Francis

John Herrmann	Y	Jan72023	11:51:20	WI DNR Wolf Management Plan	I have reviewed the WI wolf management plan and strongly disagree with most of it. I agree with the 32 objections that have been submitted by the Wisconsin Wildlife Federation and hope the WI DNR will change the plan. I have lost all faith in the WI DNR and feel like the DNR is controlled by special interest groups. This wolf plan shows that I am correct. John Herrmann Chippewa County
Tim Lobner	Y	Jan72023	13:20:53	Wolf Plan	I disagree with you wolf plan. There should be no plan without a max goal number of wolfs.Any one that spends any time in the outdoors, knows your estimate is way low.You obviously don't listen to people who are most involved. I also disagree with the buffer zone.It is unfair to land owners who live in these zones.I don't feel the tribes should be dictate the policy off reservation. Timothy Lobner Wis Rapids
Kailee Krenz	Unknown	Jan82023	8:16:14	Wolf Management Plan Comment	Hello this is John Clements, a member of the Wisconsin Bear Hunters Association. We bear hunt in Douglas County and I wanted to let you know that the wolf population has exploded, at anytime on our cameras you can see 3-4 wolves per picture. Our baits are spread out around 20 miles and every bait has wolves on it no matter the time of day. You are taking away our right to run dogs by having so many wolves that you can not control them, and I am not the only hunter that thinks so. I am not for killing all of the wolves, but we have to have a manageable herd. Wolves have no natural predator, we have to take care of this problem. Sincerely yours, John Clements If you have any questions, please call [redacted]
Kailee Clements	Unknown	Jan82023	8:34:22	Wolf Management Plan Comment	Hello this is Kailee Clements - (maiden name Krenz). I have bear hunted my whole life, when I was young with my father in the Birchwood area and now with my husband and his family in Douglas county. This is a sport that I truly enjoy with my family when I was younger and now get to continue to enjoy with my family that my husband and I are continuing to create. I had no fear in the woods growing up, my dad always told me that humans were the species that ran the woods, and now that is a completely different story. I was 9 years old the first time I had to witness what a pack of wolves can do to a hound in 'their' territory and I will never forget the image I saw in the woods that day, and I will continue to remember it everytime I check a camera and see 3-4 wolves throughout the night and day. I am now 25 years old and there are multiple times per week/weekend that we have to avoid even getting our hounds out in fear of them being overrun by the outrageous number of wolves in Douglas county. If the wolf population does not become managed I fear that bear hunting will be a dying sport and my children will not be able to continue doing what my family has done their whole lives. The wolves in Douglas county alone are very out of control and I am worried about my dogs and a sport that I hold dear to my heart. I do not think that wolves should be taken out as a whole, but I do think that there should be some sort of management action taken care of. Thank you for taking the time out to read my opinion and point of view, Sincerely - Kailee Clements
Bill Herrmann	Y	Jan82023	9:16:56	Wolf Management Plan	I have hunted and fished in Wisconsin for the last 79 years. After reviewing the Wolf Management Plan I strongly disagree with almost all of it. I do agree with the 32 objections that have been submitted by the WWF. I hope the NRB will in no way approve this plan. This plan shows why I have no faith in the current DNR on their handling of any wildlife issues. As a long time former member of the Wisconsin Conservation Congress from Chippewa County it saddens me to see the present state of the DNR. William Herrmann Chippewa County
John Herrmann	Y	Jan82023	12:54:27	Fwd: Wolf Management Plan	I have hunted and fished in Wisconsin for the last 79 years. After reviewing the Wolf Management Plan I strongly disagree with almost all of it. I do agree with the 32 objections that have been submitted by the WWF. I hope the NRB will in no way approve this plan. This plan shows why I have no faith in the current DNR on their handling of any wildlife issues. As a long time former member of the Wisconsin Conservation Congress from Chippewa County it saddens me to see the present state of the DNR. William Herrmann Chippewa County
John Romans	Y	Jan92023	17:31:05	Wisconsin DNR C/O Wolf Management Plan	Wolf management in Wisconsin should not be a difficult endeavor. Politics and people's misguided or sympathetic views run rampant. Most people (hunters and non hunters alike) in this state seem to understand the ecosystem and the need for all of our wildlife to flourish. The problem with the wolf management plan is this; Why do wolves get special treatment at the expense of other wildlife? The northern deer herds in Douglas and Bayfield counties are decimated because of the DNR's unwillingness to control the Wolf Packs. Why are Wolves more important than deer (our number one hunting resource for revenue)? The goal is to have Wolves in Wisconsin. Then manage them with a numerical goal like every other big game animal. 350 is the number most people agree on. I believe the Wisconsin Wildlife Federation and Conservation Congress has a better proposal to the DNR Wolf Plan. Please accept all 32 objections by the WWF. Take into account the people that live with the wolves, not people in a town or on a lake shore in Wolf range. Then rework the Wolf Plan so all Wisconsin outdoors people can live, hunt and experience the Northern TImber Wolf. First and foremost is the delisting of Wisconsin Wolves. Then manage them like any other big game. Respectfully, John Romans Centuria, Wisconsin
Ann Tagawa	Unknown	Jan92023	19:05:54	Protection of gray Wolves	Dear Decision Makers, I write as a concerned citizen to ask you to please do whatever you can to reduce the number of wolves that are killed in Wisconsin. It is so important to protect them to maintain balance in our ecosystems and to respect their right to live as the magnificent animals they are. Thank you for doing whatever you can to protect our wolves! Sincerely, Ann Tagawa [redacted]
Steven Waskow	Unknown	Jan112023	7:02:40	Wolf Management Plan	To WDNR, I am writing to express my concerns with the recently announced 'Wolf Management Plan'. Why is there no longer a population goal? Why are the Tribes being given partial control of lands surrounding the Reservation in the form of a buffer zone. When wolf management was proposed I don't remember how many years ago, we had population goals set as a number of wolves in Wisconsin. How are they going to be managed now? How many square miles are in the 6- mile buffer zones? what are they going to be? who will determine what is allowed on them? The state or the Tribes. Have we in essence just made to reservations larger. I feel like we've caved in completely to antihunting and tribal interests without considering hunters, landowners, or business owners in Northern Wisconsin. Steven Waskow [redacted]
Kevin Hogie	Unknown	Jan112023	9:10:56	Wolf plan objections	To whom it may concern, We have property in NW Wisconsin. The wolves in our area are out of control. The wolves need realistic management goals, back to 350? Thank you, Kevin Hogie [redacted]
Amber Kern	Unknown	Jan112023	19:56:07	Wolf population	Once again groups that have no idea about the wolf populations we face in our area are trying to stop wolf hunts that control their populations. As someone who has had multiple encounters with these wolves in my own yard, once while holding my sleeping toddler on my lap while mowing, where I had 3 extremely large wolves circling me and jumping at each other in the air to bite at each other when they passed in the circle, I feel I have a right to have a voice in this issue. The others do not! The wolves around here are getting more brave and more aggressive. Multiple people have felt threatened by them, including myself who has had more than one run in with them approaching me in my yard. The numbers need to be capped statewide using the matrix number of 350. And the six mile buffer zone around tribal land is also wrong. Hunting is a big deal in Wisconsin and brings in a lot of revenue for the state. The wolf populations are a huge threat to the deer populations and a threat to successful hunting. Many hunters have stopped coming here to hunt because they only see wolf tracks and no deer. Hunting is not a hobby. It feeds my family for many meals. We rely on venison to help feed this family. People who don't hunt and don't have wolves in their back yards have not earned a right to speak on these issues. We are not wolf haters. We only ask for population control and even relocating them to the other areas that are not having issues. I hope you will hear the concerns of those this actual impacts. Thank you, The kern family Larry, Amber, Brandon, Nicholas, William, and Savannah

Cole J Correia	Unknown	Jan122023	11:47:25	FW: Wisconsin Wolf Hunting	Hello DNR and WOlf Advocates, I'm writing this email to speak my voice on wolf hunting in Wisconsin, I understand the need to keep the population at a stable point, but in recent years hunters have been abusing this and killing double the limit of wolves. A lot of overkilling stems from the misconception that wolves are maneaters, they'd rather be left alone than attack a human, sometimes they may kill cattle but they are wild animals that need to eat like the rest of us, and plus farmers get compensation for the murder of cattle anyway. Wolves help the ecosystem stay balanced and healthy by hunting herbivores that if left unchecked would destroy the plants of their given ecosystem, this very thing happened in Yellowstone, they had to bring foreign wolves in just to fix it. As someone who understands and appreciates the positive impact wolves have on the ecosystem, I kindly request to put more thought into making wolf hunting season a less common event. Sincerely, Cole
Barb Ament	Y	Jan122023	14:21:49	DNR Wildlife Switchboard - Wolves	DNR Wildlife Switchboard My family and I have been longtime Northern Wisconsin residents. We are not opposed to wolves, but they must be managed to a minimum number of 350 or less, as they are totally out of control now. Please do not allow wolves to populate in low quality wolf habitat as this will create many conflicts and enforce the delisting of wolves. Kirby Ament [redacted] Somerset, WI 54025 [redacted]
Todd Knutson	Unknown	Jan122023	15:46:10	DNR Wolf Management Plan	To Whom It May Concern, I wanted to share my comments regarding the newly released DNR Wolf Plan. I currently own 440 acres of recreational land in Douglas County. This property has been in our family for three generations, which has primarily been used for deer hunting. Over the years, the deer population has been slowly dwindling due to the excessive numbers of predators. The one predator, which has evated much if any management is the wolf. My interest in reducing the number of wolves living in NW Wisconsin is very high not only for my own personal reasons but, for the other property owners and businesses located in Douglas County. In regard to the proposed Wolf Management Plan, here are my thoughts: * Please establish a matrix number to cap the wolf population. We are currently at the point of no return, where management won't be able to keep the population in check. Even though the number of wolves harvested in the 2021 hunt went over the harvest quota, there were no wolves killed within miles of our property. In fact, the current number of encounters, pictures, deer kills, etc., are higher now than before the 2021 hunt. * I'm totally against the proposed six-mile buffer zone around Tribal Nations. I can't imagine what property values would do to the folks that own property next to a reservation with this language in place. Plus, you would be restricting the hunting rights of property owners. At the end of the day, I just want to see an annual wolf season take place! Obviously, nobody involved is going to come out of this as a winner. Yes, wolves belong on the landscape but, like every other animal needs management too! One other suggestion would be for the DNR to be more proactive with legal proceedings which help hunters and trappers alike. I realize anti-huntingers contribute a lot of funding toward political campaigns and attorneys to fight delisting the wolf. Hunters and Trappers pay a lot of money as well toward wildlife management and help to fund the DNR. Thank you for your time, Todd Knutson
Linda Ruechel	Unknown	Jan152023	15:11:44	Wolf Plan	Issues with the proposed wolf plan. 1- Provide a timeline for the numeric wolf population goal in the final plan. 2- Maintain 350 wolf population goal with a timeline for achieving this goal by managing the current population. 3- Include lone and dispersing wolves in the population estimates similar to the estimates of 12%-15% in Idaho and Montana. 4- Remove or reduce the buffer zones around Indian reservations which restrict or prohibit non-tribal members from hunting or trapping on our own land, which includes farmers who are impacted by wolves. 5- Counties not affected by wolves use USDA Wildife Services to control wolf damage instead of allowing hunters and trappers to remove these animals. 6- The plan doesn't sufficiently address depredations of non-agriculture domestic animals, such as dogs. All legal methods of harvesting should be included in the plan. 7- The plan definitely holds biases against hunting with dogs implying that any hunting conflicts are the fault of the hunter. Hunting with hounds has the same statutory and state constitutional protections as agriculture and should have equal active measures to prevent depredations through controlled management of wolves. 8- The draft lacks active conflict management in heavy depredation of dogs and non-agriculture animals. 9- Address the psychological impacts on humans due to wolf conflicts 10- Base the zone restructure on science-based suitable habitat. Not all areas are appropriate for wolves. 11- Wolves should be managed to reside in high-quality wolf habitat and not be managed to the maximum biological carrying capacity. 12- Western states have been unable to reduce wolf numbers consistently despite high levels of human interest. 13- Wolves are prolific, disperse long distances, readily recolonize new areas wherever humans will allow them and are difficult to control. 14- Federal delisting is required for conflict control and population management. We need the DNR to have a strong and visible presence with active involvement in all federal delisting efforts that impact Wisconsin, and in support of all other states actively working toward delisting and managing wolves in their states.
Joni Hogie	Y	Jan162023	18:33:14	Wolf Management Plan Objection	Wisconsin DNR, I would like to express my objections to the Plan you have proposed for Wolf Management: As residents of Douglas County, we are constantly inundated with wolves. I find it unbalanced that people who live/work several hours away ('Plan Writers and Key Contributors'), and are all funded by the government, are the people creating this plan. Not one person on your planning commission is a resident of our county, where wolves are a daily threat, yet you want us to adhere to your 'scientific' methods of managing wolves. How many of your writers/contributors have ever spent any amount of time in the woods of Douglas County? We've often offered our proof (trail camera photos, photos of tracks, face-to-face encounters, etc. see below photo) of the incredible amount of wolves in our area, but the DNR folks we've contacted were not interested because they're using a scientific algorithm! What's more accurate than actual sightings and photographs? Have any of your committee members ever had to stand outdoors hovering close to your pets while they relieve themselves because you can hear the wolves howling nearby? Have any of you ever had to worry about your children/grandchildren playing outside because your trail cameras took photos of wolves the night before?! How about we move wolf packs into the cities where your members and the folks in the wolf expansionist groups live? After all, those areas were habitats for wildlife once upon a time. By your own document's wording (page 5), 'research continues to show how adaptable wolves are and the variety of factors which play into the habitats they are willing and able to use'. If you want to increase the amount of wolves in Wisconsin, then spread them out equally so that everyone can experience having wolves as neighbors. This is from a trail camera on Town Road TT in Dairyland, WI. Less than 3 months ago. There are 9 wolves at this deer kill. We have several other photos too. We are not anti wolf. We consider ourselves stewards of the land and love/appreciate all wildlife. Our land is our life. All creatures (including humans) deserve to live and cohabitate in the wilderness together. The 1999 plan established the quantity at 350 wolves. Please keep to your original quota. Since the start of the pandemic, there has been an influx of people moving into our area. That alone should be justification that the habitat for wolves has been reduced since the original plan (so perhaps the number should be less than 350?). There is not as much room any more. Adding more wolves to your count would be perilous to the wolves as well as dangerous to the residents and their pets/livestock. Stop reinventing the wheel. The western states have used successful research and methodologies (i.e. iPOM - see https://thewesternnews.com/news/2022/aug/12/wolf-report-shows-stable-population-numbers-throug/<https://secure-web.cisco.com/1I9C163fC1dV-T4UmEYEb7lHH2xxJ8pelQLhdw-xh1rGhuiKmE_voU8L7kgpwFQdREto85Gj0BNwY9PG7jS-SQaQGXuSfzAE2gupGmsjpLDtbtOFSf8HBp-kVrGszZGGcQeXFCMriEYF6Ttra9SjLCE1upB5oZzMDsZCe6djHVWV6OeVoOn0h9LnUW39u8k99aMNaPTYSSqu23af8h5xU7QHpCxHUyLCcHq8Oc56dZgMQkrERBn3c-kqu3DiHs350uTiwEZMXzXGO2Qh-K3DYuwwtDYSSuURND8Hrpacz-

					ZBa_Sg8UpGO5hkwjAeaN0CFRa6Yj1zys7tLCpH_tyNkkQ/https%3A%2F%2Fthewesternnews.com%2Fnews%2F2022%2Faug%2F12%2Fwolf-report-shows-stable-population-numbers-throug%2F>) that could easily be utilized in Wisconsin. Their methodologies incorporated scientific devices as well as input from hunters/residents. Employing tried and true approaches and procedures would be productive and cost effective (saving tax payer's dollars). I also ask that the DNR be more proactive in the push to get wolves delisted. We do not see our Wisconsin DNR making much of any effort in influencing the federal delisting. People in far away states tend to listen to those making the most noise, not necessarily those who are directly impacted by the conflicts with the wolf population. The number of wolves in our Douglas County are out of control, unbalanced, unfair, and dangerous to wildlife, habitat, and humans. Please adjust your Plan accordingly. In appreciation, Joni Dairyland, WI wolves are and the variety of factors which play into the habitats they are willing and able to use.
Peter Smith	Unknown	Jan182023	14:57:18	Fw: Protect wolves in Wisconsin!	Wisconsin Wolves Change Rivers! Mr. Peter Smith Chief Executive Officer CAVE MAN ENVIRONMENTAL CONSULTING Bringing rational decision making back to Government E Mail: [redacted]
Anna Oberoi	Unknown	Jan182023	14:57:53	Protect Wolves!	I support increasing protections for wolves, requiring non-lethal conflict interventions and banning recreational killing and I hope you do too!
Nancy Fleming	Unknown	Jan182023	15:12:16	Wisconsin Wolf Management Plan	I am writing in reference to the proposed Wisconsin Wolf Management Plan. This plan should strictly curtail any lethal management of wolves except in extremely rare circumstances of immediate defense of life. A substantial body of research documenting human-caused mortality in North American wolves, including Wisconsin wolves, has found that policies allowing liberalized killing of wolves result in a direct increase in the hazard and incidence of illegal killings. These Alpha predators are an extremely important part of the Wisconsin ecosystem and deserve our protection. The impact of widespread killing on wolves' physiology, behavior, wellbeing, social dynamics of wolf packs must be considered. Thank you for your consideration of this important matter. With Kind Regards, ~Nancy Fleming
Marilyn Price	Unknown	Jan182023	15:19:15	Your Draft Wolf Management Plan	To whom it may concern, I receive emails from Center for Biological Diversity and received one today on your Draft Wolf Management Plan. My concern in general is the rapid decline in biological diversity in this country and around the world. I am most grateful for the work done groups such as Center for Biological Diversity and hope you read and follow the advice they are giving you on your Draft Wolf Management Plan. Thank you for considering my request. Marilyn Price

kevin cook	Unknown	Jan182023	15:36:29	Wolves	Protect them!!
C Serotini	Unknown	Jan182023	15:39:43	Wildlife	Please stop the killing of animals that are living in their environment. It's senseless, cruel, greedy. All beings on earth belong, just not killers!
Christina DeRespiris	Unknown	Jan182023	15:40:21	Wolf Management Plan	I appreciate the efforts of all WDNR staff involved in updating the state's wolf management plan. Although I believe the current plan needs significant updating (see next section), I recognize the efforts and improvements made to the previous plan, including: ● Wolves in WI will no longer be managed by reference to the old numerical goal of 350 wolves ● There is much greater recognition of the ecological role of wolves ● The inclusion of a social survey, which notes increased positive views of wolves, knowledge of their ecological roles and increased opposition to the motives and methods for killing wolves ● The adoption of proposed buffer zones around tribal reservations (i.e., previously no buffer zones existed) What I don't like: ● The current draft does not reflect the best available science, and is missing a substantial amount of scientific literature on (see reference list below): ● wolf ethology, sentience, sapience, sociability, agency and wellbeing ● effectiveness of non-lethal interventions, especially relative to lethal ones ● the impact of widespread killing on wolves' physiology, behavior, wellbeing, social dynamics, ecological relationships and evolution ● The above scientific omissions, combined with the emphasis on and promotion of sustainable recreational killing and consumptive users as a main management strategy, results in a biased plan that runs contrary to scientific evidence despite much of this omitted scientific evidence being more recent, numerous and of stronger inference. ● The plan should strictly curtail any lethal management of wolves except in extremely rare circumstances of immediate defense of life. ● A substantial body of research documenting human-caused mortality in North American wolves, including Wisconsin wolves, has found that policies allowing liberalized killing of wolves result in a direct increase in the hazard and incidence of illegal killings. ● Hounding or hound training, which are akin to allowing legalized dogfighting, should be illegal or severely restricted as this practice is extremely cruel to wolves and hounds alike and is not supported by the majority of hunters or the broad public. ● The plan should prioritize wolf protections and concentrate solely on non-lethal management of wolves in response to livestock conflicts to ensure ethical coexistence. ● Despite Act 169, which mandates a wolf hunting season, the department can still restrict the implementation of lethal methods by setting minimal quotas, including a quota of '0' wolves, restricting timing and methods. ● Several studies have proven a proactive non-lethal approach leads to better conflict mitigation. ● Lethal management often fails to provide a long-term solution to wolf predation and has the least consistent success rates when compared to non-lethal practices. In addition, there is significant evidence showing that lethal wolf management may be less functionally effective at mitigating subsequent livestock losses than non-lethal deterrents. ● The plan should require the implementation of abatement measures as well as the use of non-lethal conflict minimization techniques by domestic animal owners for the latter to receive compensation for confirmed predation. ● The plan also runs contrary to public values towards wolves (and omits mention of such majority values from the plan), despite department surveys evidencing that the broad public cares about wolves as individuals (and not just for the viability of the population). Given the recent liberalization of killing wolves by the state, it would be incredibly informative to note majority support of the following reasons for opposing a regulated wolf hunting/trapping season (which are all omitted from the plan): opposition to specific methods of harvest like hounds (64%) or traps (70%), feelings that hunting wolves is unnecessary (62%) or culturally offensive to Native American tribes (57%). ● All such reasons convey majority disagreement with practices currently promoted and endorsed by the legislature and the WDNR, and such a conflict between managers and the public should not only be acknowledged, but foregrounded and carefully considered in policy (instead of dismissed). ● Such decisions to omit literature or downplay evidence (e.g., such as majority opposition to killing wolves and their reasons) are contrary to principles of scientific integrity (e.g., present all relevant scientific evidence to the public) as well as ethics (e.g., disguising ethical decisions, such as recreational wolf killing, as robustly supported by science). ● Conflicting agency objectives (e.g., optimizing public hunting and conflict mitigation) are not only not acknowledged, but even misunderstood as harmonious, against the body of scientific evidence. That culminates in the prioritization of consumptive values and policies; e.g., according to the body of scientific literature, use of lethal methods, and 2 especially public hunts, are contrary to most objectives relevant to: harm

Name	Resident	Date	Time	Subject	Email Body
					mitigation, the wellbeing of wolves, their ecological roles, and their non-exploitative enjoyment (i.e., Objectives A, B, D and F). ●⍰ There is a stark lack of consideration for individual wolves, wolf population health (including wellbeing), and measurable indicators for assessing any harms barring disease prevalence (e.g., accounting for cortisol levels or other stress hormones, measures of pair/pack persistence) ●⍰ There is an inappropriate understanding and consideration of tribal worldviews about wolves. Tribal worldviews of wolves are misconstrued as 'cultural benefits' tribes receive from the existence of a wolf population, when in fact tribal worldviews consider each individual wolf as a person and relative. Cultural respect and sensitivity towards such views, shared by many non-tribal members, demand the strict mitigation of lethal measures, especially recreational killing, as opposed to their current promotion in the plan. ●⍰ In general, all omissions of scientific literature, the arbitrary prioritization of policy objectives, the rhetoric of the plan and the dismissal of public values and concerns for wolves point towards a biased, unscientific and instrumental view of wolves that promotes values contrary to broad public perspectives on wolves. ●⍰ 'SOM' wolf estimation methodology " From a recent critique: The new methods sacrifice precision, but are believed to retain adequate accuracy and sensitivity to changing conditions for reliable decision-making. We review evidence for the accuracy, precision, and sensitivity of the new 'scaled occupancy model' (SOM) applied in Wisconsin. We conclude that the Wisconsin method would systematically overestimate wolf abundance by large (but currently incalculable) margins. Because Wisconsin, similar to other states, not only changed to unverified methods but also implemented widespread wolf killing, shortcomings in their estimates of wolf abundance may have far-reaching consequences for population viability and confidence in state wildlife managers. We discuss findings from Wisconsin alongside similar findings for other states' occupancy models being insensitive to human causes of mortality that have recently increased. Overall, Wisconsin's proposed method for estimating wolf abundance shows significant departures from best practices in scientific measurement. Verification will require independent replication and unbiased tests at multiple scales in multiple habitats under different human-induced mortality rates, and peer review before the new methods are considered reliable.⍰ (Treves & Santiago-Ã⍰vila, 2023). Thank you, Christina DeRespiris [redacted]
Fred Elliott	Unknown	Jan182023	15:49:32	Protection of wolves	Please protect the wolves. Thank you Fred Elliott
Paul Martin Griepentrog	Y	Jan182023	15:52:55	Wolf management plan	Paul Martin Griepentrog Mailing address [redacted] Park Falls, WI 54552 [redacted] Response to WDNR Wolf Management Plan; As one uniquely positioned to comment as my farm lies within the area proposed to be annexed for reduced wolf harvest, I have several direct and indirect encounters with wolves and USDA WS. I have lived here for over 20 years and hold a masters certificate in wild life biology and animal damage control from the University of Purdue. The first three wolves I encountered where infected with sarcoptic mange, an indication of overpopulation. The fourth was 20 feet from my back door. I will not venture into any wooded area without a firearm for protection. I have had sheep deprivation confirmed by USDA APHIS in the past, but no longer have them due to infection of brain worms from deer. The claim of USDA WS being available 24/7 is false, I contacted the Rhinelander office in April with no response until I called a week later. Current WS conduct is to ignore injury. Will the abatement requirements for wolves be similar to deer? Where I was required to provide labor to erect and maintain abatement protocols. Does this not constitute extorting performance under color of law without just compensation? Isn't the claim of benefit from wolves reducing CWD, browsing new forest growth by deer, and deer car incidents, rooted in an overpopulation of deer? Why is there no testing data for diseases known to be transferred by wolves to livestock ex. Neosporosis, humans ex. Oocysts that linger in the soil and are fatal, or the recent discovery of parasite in wolves that increases their aggression? If we don't look is it not there? Does the maps and data provided indicating livestock deprivation as a result of prior wolf management indicate willful intent to do harm or depraved indifference on the part of the WI DNR, or both? Would the annexation of my lands into a reduced harvest quota be violative of rights granted me by assent to Federal Land Patent 2171 & 2101 document number 347541 Price Co.? Does not silence equate as fraud in it's elemental form of deceit, where there is a fiduciary duty to speak? See Black's Law 6th Edition
Srhein	Unknown	Jan182023	15:59:58	Protect Wolves in Wisconsin	Wolves are at the top of the food chain in the wild, and the loss of wolves disrupts nature's plan. We appreciate the efforts of all WDNR staff involved in updating the state's wolf management plan. Given the recent liberalization of killing wolves by the state, it would be incredibly informative to note majority support of the following reasons for opposing a regulated wolf hunting/trapping season (which are all omitted from the plan): opposition to specific methods of harvest like hounds (64%) or traps (70%), feelings that hunting wolves is unnecessary (62%) or culturally offensive to Native American tribes (57%). ● All such

Name	Resident	Date	Time	Subject	Email Body
					reasons convey majority disagreement with practices currently promoted and endorsed by the legislature and the WDNR, and such a conflict between managers and the public should not only be acknowledged, but foregrounded and carefully considered in policy (instead of dismissed). ● Such decisions to omit literature or downplay evidence (e.g., such as majority opposition to killing wolves and their reasons) are contrary to principles of scientific integrity (e.g., present all relevant scientific evidence to the public) as well as ethics (e.g., disguising ethical decisions, such as recreational wolf killing, as robustly supported by science). ● Conflicting agency objectives (e.g., optimizing public hunting and conflict mitigation) are not only not acknowledged, but even misunderstood as harmonious, against the body of scientific evidence. That culminates in the prioritization of consumptive values and policies; e.g., according to the body of scientific literature, use of lethal methods, and 2 especially public hunts, are contrary to most objectives relevant to: harm mitigation, the wellbeing of wolves, their ecological roles, and their non-exploitative enjoyment (i.e., Objectives A, B, D and F). ● There is a stark lack of consideration for individual wolves, wolf population health (including wellbeing), and measurable indicators for assessing any harms barring disease prevalence (e.g., accounting for cortisol levels or other stress hormones, measures of pair/pack persistence) ● There is an inappropriate understanding and consideration of tribal worldviews about wolves. Tribal worldviews of wolves are misconstrued as 'cultural benefits' tribes receive from the existence of a wolf population, when in fact tribal worldviews consider each individual wolf as a person and relative. Cultural respect and sensitivity towards such views, shared by many non-tribal members, demand the strict mitigation of lethal measures, especially recreational killing, as opposed to their current promotion in the plan. ● In general, all omissions of scientific literature, the arbitrary prioritization of policy objectives, the rhetoric of the plan and the dismissal of public values and concerns for wolves point towards a biased, unscientific and instrumental view of wolves that promotes values contrary to broad public perspectives on wolves. ● 'SOM' wolf estimation methodology “ From a recent critique: The new methods sacrifice precision, but are believed to retain adequate accuracy and sensitivity to changing conditions for reliable decision-making. We review evidence for the accuracy, precision, and sensitivity of the new 'scaled occupancy model' (SOM) applied in Wisconsin. We conclude that the Wisconsin method would systematically overestimate wolf abundance by large (but currently incalculable) margins. Because Wisconsin, similar to other states, not only changed to unverified methods but also implemented widespread wolf killing, shortcomings in their estimates of wolf abundance may have far-reaching consequences for population viability and confidence in state wildlife managers. We discuss findings from Wisconsin alongside similar findings for other states' occupancy models being insensitive to human causes of mortality that have recently increased. Overall, Wisconsin's proposed method for estimating wolf abundance shows significant departures from best practices in scientific measurement. Verification will require independent replication and unbiased tests at multiple scales in multiple habitats under different human-induced mortality rates, and peer review before the new methods are considered reliable. (Treves & Santiago-Ãvila, 2023)
Judy Oates	Unknown	Jan182023	16:00:52	Please Protect Wplves	Wolves are an important part of our ecosystem. Please provide protection for them.
R Wenthold	Unknown	Jan182023	16:10:56	Wolves in WI	Please stop the hunting as these animals are essential to the environment and do not require being culled.
Diane M Kastel	Y	Jan182023	16:21:16	What we do NOT like:	We appreciate the efforts of all WDNR staff involved in updating the state's. wolf. management plan. Although we believe the current, plan needs, significant, updating , we recognize the efforts and improvements made to the. previous. plan, including: ● Wolves, in WI, will no longer be managed by reference to the. old. numerical goal of 350 wolves. ● There is, much, greater recognition of the, ecological, role of wolves ● The inclusion of a, social, survey, which notes, increased, positive views of wolves, knowledge of their, ecological, roles, and, increased, opposition to the motives, and, methods, for killing wolves ● The adoption of, proposed, buffer zones around, tribal, reservations (i.e., previously, no buffer zones existed) What we do NOT like: ● In general, all, omissions of, scientific, literature, the, arbitrary, prioritization of, policy, objectives, the rhetoric of the plan, and, the dismissal of, public, values, and, concerns, for wolves point towards a biased, unscientific, and, instrumental, view of wolves that promotes values contrary to, broad, public perspectives on wolves! ● 'SOM', wolf, estimation methodology “ From a, recent, critique: The, new, methods sacrifice precision, but, are believed to retain, adequate, accuracy and, sensitivity, to, changing, conditions for, reliable, decision-making! We review evidence for the accuracy, precision, and, sensitivity of the, new, 'scaled occupancy model' (SOM) applied in Wisconsin. We conclude that the, Wisconsin, method would, systematically, overestimate, wolf, abundance by large (but, currently, incalculable) margins. Because Wisconsin, similar to, other, states, not only changed to, unverified, methods, but, also, implemented, widespread, wolf killing, shortcomings in their estimates of, wolf, abundance may have, far-reaching, consequences for, population, viability, and, confidence in, state, wildlife managers! We discuss findings from Wisconsin alongside similar, findings for, other, states' occupancy models being insensitive to, human, causes of mortality that have, recently, increased! Overall, Wisconsin's, proposed, method for estimating, wolf, abundance shows, significant, departures from, best, practices in, scientific, measurement. Verification will require, independent, replication, and, unbiased, tests at, multiple, scales in, multiple, habitats under, different, human-induced mortality rates, and, peer, review before the, new, methods are considered reliable. (Treves & Santiago-Ãvila, 2023) ● The, current, draft does NOT reflect the, best,, available science, and, is missing a, substantial, amount of, scientific, literature on: ● wolf ethology, sentience, sapience, sociability, agency, and, wellbeing ● effectiveness of, non-lethal, interventions, especially, relative to, lethal, ones ● the impact of, widespread, killing on wolves' physiology, behavior, wellbeing, social dynamics, ecological, relationships, and, evolution! ● The, above, scientific omissions, combined with the emphasis on, and, promotion of, sustainable, recreational killing, and, consumptive, users as a, main, management strategy, results in a, biased, plan that runs contrary to, scientific, evidence despite much of this, omitted, scientific evidence being, more, recent, numerous, and, of, stronger, inference! ● The plan MUST, strictly, curtail, any, lethal management of wolves except in extremely, rare circumstances of, immediate, defense of life! ● A, substantial, body of research documenting, human-caused, mortality in, North American, wolves, including, Wisconsin, wolves, has found that policies allowing, liberalized, killing of wolves result in a, direct, increase in the hazard, and, incidence, of, illegal, killings! ● Hounding, or, hound, training, which are akin to allowing, legalized, dogfighting, MUST be illegal, or, severely, restricted as this practice is, extremely, cruel to wolves, and, hounds, alike, and, is NOT supported by the majority of hunters, or, the, broad, public! ● The plan MUST prioritize, wolf, protections, and, concentrate, solely, on, non-lethal, management of wolves in response to, livestock, conflicts to ensure, ethical, coexistence! ● Despite Act 169, which mandates a, wolf, hunting season, the Department can, still, restrict the implementation of, lethal, methods by setting, minimal, quotas, including a quota of '0' wolves, restricting timing, and, methods! ● Several studies have proven a, proactive, non-lethal approach leads to, better, conflict mitigation! ● Lethal management fails to provide a, long-term, solution to, wolf, predation and, has the, least, consistent success rates when compared to, non-lethal, practices! In addition, there is, significant, evidence showing that, lethal, wolf management is, less, functionally, effective at mitigating, subsequent, livestock losses than, non-lethal, deterrents! ● The plan MUST require the implementation of, abatement, measures as well as the use of, non-lethal, conflict minimization techniques by, domestic animal owners for the latter to receive compensation for, confirmed, predation! ● The plan, also, runs contrary to, public, values towards wolves (and, omits mention of, such, majority values from the plan), despite, Department, surveys evidencing that the, broad, public cares about wolves as individuals (and, NOT just for the viability of the population)! Given the, recent, liberalization of killing wolves

					by the state, it would be demonstrably, informative to note, majority, support of the, following, reasons for opposing a, regulated, wolf hunting/trapping season (which are, all, omitted from the plan): Opposition to, specific, methods of harvest, like hounds, (64%), or, traps (70%), feelings that hunting wolves is unnecessary (62%), or, culturally, offensive to Native American tribes (57%). ● All, such, reasons convey, majority, disagreement with practices, currently, promoted and endorsed by the legislature, and, 'WDNR, and, such, a conflict between managers, and, the public, should not only be acknowledged, but, foregrounded, and, carefully, considered in policy (instead of dismissed)! ● Such decisions to omit literature, or, to downplay evidence (e.g., such as, majority, opposition to killing wolves and their reasons) are contrary to principles of, scientific, integrity (e.g., present, all, relevant, scientific evidence to the public) as well as ethics (e.g., disguising, ethical, decisions, such as recreational, wolf killing, as, robustly, supported by science)! ● Conflicting Agency, objectives (e.g., optimizing, public, hunting, and, conflict, mitigation) are not only NOT acknowledged, but, even, misunderstood as harmonious, against the body of, scientific, evidence! That culminates in the prioritization of, consumptive, values, and, policies; e.g., according to the body of, scientific, literature, use of, lethal, methods, and, especially, public, hunts, are contrary to, most, objectives relevant to: harm mitigation, the wellbeing of wolves, their, ecological, roles, and, their, non-exploitative, enjoyment (i.e., Objectives A, B, D and F)! ● There is a, stark, lack of consideration for, individual, wolves, wolf, population health (including wellbeing), and, measurable, indicators for assessing, any, harms barring disease prevalence (e.g., accounting for, cortisol, levels, or, other, stress hormones, measures of, pair/pack, persistence)! ● There is an, inappropriate, understanding, and, consideration of, tribal, worldviews about wolves. Tribal worldviews, of wolves, are misconstrued as 'cultural benefits' tribes receive from the existence of a, wolf, population, when in fact, tribal, worldviews consider, each, individual wolf as a person and relative. Cultural respect, and, sensitivity, towards, such, views, shared by, many, non-tribal members, demand the, strict, mitigation of, lethal, measures, especially, recreational, killing, as opposed to their, current, promotion in the plan! DIANE M. KASTEL AND FAMILY RACINE, WI
Gisele Albertine	N	Jan182023	16:22:53	Wisconsin Department of Natural Resources	To Whom it May Concern, The Draft Wolf Management Plan is slightly improved but needs much greater changes because it still does not reflect the best available science, ethics, and broad public values that should guide wolf police and coexistence. The current draft is missing a substantial amount of scientific literature on: - wolf ethology, sentience, sapience, sociability, agency and wellbeing - effectiveness of non-lethal interventions, especially relative to lethal ones - the impact of widespread killing on wolves' physiology, behavior, wellbeing, social dynamics, ecological relationships and evolution - The above scientific omissions, combined with the emphasis on and promotion of sustainable recreational killing and consumptive users as a main management strategy, results in a biased plan that runs contrary to scientific evidence despite much of this omitted scientific evidence being more recent, numerous and of stronger inference. - The plan should strictly curtail any lethal management of wolves except in extremely rare circumstances of immediate defense of life. - A substantial body of research documenting human-caused mortality in North American wolves, including Wisconsin wolves, has found that policies allowing liberalized killing of wolves result in a direct increase in the hazard and incidence of illegal killings. - Hounding or hound training, which are akin to allowing legalized dogfighting, should be illegal or severely restricted as this practice is extremely cruel to wolves and hounds alike and is not supported by the majority of hunters or the broad public. - The plan should prioritize wolf protections and concentrate solely on non-lethal management of wolves in response to livestock conflicts to ensure ethical coexistence. - Despite Act 169, which mandates a wolf hunting season, the department can still restrict the implementation of lethal methods by setting minimal quotas, including a quota of '0' wolves, restricting timing and methods. - Several studies have proven a proactive non-lethal approach leads to better conflict mitigation. - Lethal management often fails to provide a long-term solution to wolf predation and has the least consistent success rates when compared to non-lethal practices. In addition, there is significant evidence showing that lethal wolf management may be less functionally effective at mitigating subsequent livestock losses than non-lethal deterrents. - The plan should require the implementation of abatement measures as well as the use of non-lethal conflict minimization techniques by domestic animal owners for the latter to receive compensation for confirmed predation. - The plan also runs contrary to public values towards wolves (and omits mention of such majority values from the plan), despite department surveys evidencing that the broad public cares about wolves as individuals (and not just for the viability of the population). Given the recent liberalization of killing wolves by the state, it would be incredibly informative to note majority support of the following reasons for opposing a regulated wolf hunting/trapping season (which are all omitted from the plan): opposition to specific methods of harvest like hounds (64%) or traps (70%), feelings that hunting wolves is unnecessary (62%) or culturally offensive to Native American tribes (57%). - All such reasons convey majority disagreement with practices currently promoted and endorsed by the legislature and the WDNR, and such a conflict between managers and the public should not only be acknowledged, but foregrounded and carefully considered in policy (instead of dismissed). - Such decisions to omit literature or downplay evidence (e.g., such as majority opposition to killing wolves and their reasons) are contrary to principles of scientific integrity (e.g., present all relevant scientific evidence to the public) as well as ethics (e.g., disguising ethical decisions, such as recreational wolf killing, as robustly supported by science). - Conflicting agency objectives (e.g., optimizing public hunting and conflict mitigation) are not only not acknowledged, but even misunderstood as harmonious, against the body of scientific evidence. That culminates in the prioritization of consumptive values and policies; e.g., according to the body of scientific literature, use of lethal methods, and 2 especially public hunts, are contrary to most objectives relevant to: harm mitigation, the wellbeing of wolves, their ecological roles, and their non-exploitative enjoyment (i.e., Objectives A, B, D and F). - There is a stark lack of consideration for individual wolves, wolf population health (including wellbeing), and measurable indicators for assessing any harms barring disease prevalence (e.g., accounting for cortisol levels or other stress hormones, measures of pair/pack persistence) - There is an inappropriate understanding and consideration of tribal worldviews about wolves. Tribal worldviews of wolves are misconstrued as 'cultural benefits' tribes receive from the existence of a wolf population, when in fact tribal worldviews consider each individual wolf as a person and relative. Cultural respect and sensitivity towards such views, shared by many non-tribal members, demand the strict mitigation of lethal measures, especially recreational killing, as opposed to their current promotion in the plan. - In general, all omissions of scientific literature, the arbitrary prioritization of policy objectives, the rhetoric of the plan and the dismissal of public values and concerns for wolves point towards a biased, unscientific and instrumental view of wolves that promotes values contrary to broad public perspectives on wolves. - 'SOM' wolf estimation methodology “ From a recent critique: The new methods sacrifice precision, but are believed to retain adequate accuracy and sensitivity to changing conditions for reliable decision-making. We review evidence for the accuracy, precision, and sensitivity of the new 'scaled occupancy model' (SOM) applied in Wisconsin. We conclude that the Wisconsin method would systematically overestimate wolf abundance by large (but currently incalculable) margins. Judy Masbaum	Unknown	Jan182023	18:58:44	Wolf Management Plan Comments	What we like: We appreciate the efforts of all WDNR staff involved in updating the state's wolf management plan. Although we believe the current plan needs significant updating (see next section), we recognize the efforts and improvements made to the previous plan, including: ●⍰ Wolves in WI will no longer be managed by reference to the old numerical goal of 350 wolves. ●⍰ There is much greater recognition of the ecological role of wolves ●⍰ The inclusion of a social survey, which notes increased positive views of wolves, knowledge of their ecological roles and increased opposition to the motives and methods for killing wolves ●⍰ The adoption of proposed buffer zones around tribal reservations (i.e., previously no buffer zones existed) What we don't like: ●⍰ The current draft does not reflect the best available science, and is missing a substantial amount of scientific literature on (see reference list below): ● wolf ethology, sentience, sapience, sociability, agency and wellbeing ● effectiveness of non-lethal interventions, especially relative to lethal ones ● the impact of widespread killing on wolves' physiology, behavior, wellbeing, social dynamics, ecological relationships and evolution ●⍰ The above scientific omissions, combined with the emphasis on and promotion of sustainable recreational killing and consumptive users as a main management strategy, results in a biased plan that runs contrary to scientific evidence despite much of this omitted scientific evidence being more recent, numerous and of stronger inference. ●⍰ The plan should strictly curtail any lethal management of wolves except in extremely rare circumstances of immediate defense of life. ● A substantial body of research documenting human-caused mortality in North American wolves, including Wisconsin wolves, has found that policies allowing liberalized killing of wolves result in a direct increase in the hazard and incidence of illegal killings. ● Hounding or hound training, which are akin to allowing legalized dogfighting, should be illegal or severely restricted as this practice is extremely cruel to wolves and hounds alike and is not supported by the majority of hunters or the broad public. ●⍰ The plan should prioritize wolf protections and concentrate solely on non-lethal management of wolves in response to livestock conflicts to ensure ethical coexistence. ● Despite Act 169, which mandates a wolf hunting season, the department can still restrict the implementation of lethal methods by setting minimal quotas, including a quota of '0' wolves, restricting timing and methods. ● Several studies have proven a proactive non-lethal approach leads to better conflict mitigation. ● Lethal management often fails to provide a long-term solution to wolf predation and has the least consistent success rates when compared to non-lethal practices. In addition, there is significant evidence showing that lethal wolf management may be less functionally effective at mitigating subsequent livestock losses than non-lethal deterrents. ●⍰ The plan should require the implementation of abatement measures as well as the use of non-lethal conflict minimization techniques by domestic animal owners for the latter to receive compensation for confirmed predation. ●⍰ The plan also runs contrary to public values towards wolves (and omits mention of such majority values from the plan), despite department surveys evidencing that the broad public cares about wolves as individuals (and not just for the viability of the population). Given the recent liberalization of killing wolves by the state, it would be incredibly informative to note majority support of the following reasons for opposing a regulated wolf hunting/trapping season (which are all omitted from the plan): opposition to specific methods of harvest like hounds (64%) or traps (70%), feelings that hunting wolves is unnecessary (62%) or culturally offensive to Native American tribes (57%). ● All such reasons convey majority disagreement with practices currently promoted and endorsed by the legislature and the WDNR, and such a conflict between managers and the public should not only be acknowledged, but foregrounded and carefully considered in policy (instead of dismissed). ● Such decisions to omit literature or downplay evidence (e.g., such as majority opposition to killing wolves and their reasons) are contrary to principles of scientific integrity (e.g., present all relevant scientific evidence to the public) as well as ethics (e.g., disguising ethical decisions, such as recreational wolf killing, as robustly supported by science). ●⍰ Conflicting agency objectives (e.g., optimizing public hunting and conflict mitigation) are not only not acknowledged, but even misunderstood as harmonious, against the body of scientific evidence. That culminates in the prioritization of consumptive values and policies; e.g., according to the body of scientific literature, use of lethal methods, and 2 especially public hunts, are contrary to most objectives relevant to: harm mitigation, the wellbeing of wolves, their ecological roles, and their non-exploitative enjoyment (i.e., Objectives A, B, D and F). ●⍰ There is a stark lack of consideration for individual wolves, wolf population health (including wellbeing), and measurable indicators for assessing any harms barring disease prevalence (e.g., accounting for cortisol levels or other stress hormones, measures of pair/pack persistence) ●⍰ There is an inappropriate understanding and consideration of tribal worldviews about wolves. Tribal worldviews of wolves are misconstrued as 'cultural benefits' tribes receive from the existence of a wolf population, when in fact tribal worldviews consider each individual wolf as a person and relative. Cultural respect and sensitivity towards such views, shared by many non-tribal members, demand the strict mitigation of lethal measures, especially recreational killing, as opposed to their current promotion in the plan. ●⍰ In general, all omissions of scientific literature, the arbitrary prioritization of policy objectives, the rhetoric of the plan and the dismissal of public values and concerns for wolves point towards a biased, unscientific and instrumental view of wolves that promotes values contrary to broad public perspectives on wolves. ●⍰ 'SOM' wolf estimation methodology “ From a recent critique: The new methods sacrifice precision, but are believed to retain adequate accuracy and sensitivity to changing conditions for reliable decision-making. We review evidence for the accuracy, precision, and sensitivity of the new 'scaled occupancy model' (SOM) applied in Wisconsin. We conclude that the Wisconsin method would systematically overestimate wolf abundance by large (but currently incalculable) margins. Because Wisconsin, similar to other states, not only changed to unverified methods but also implemented widespread wolf killing, shortcomings in their estimates of wolf abundance may have far-reaching consequences for population viability and confidence in state wildlife managers. We discuss findings from Wisconsin alongside similar findings for other states' occupancy models being insensitive to human causes of mortality that have recently increased. Overall, Wisconsin's proposed method for estimating wolf abundance shows significant departures from best practices in scientific measurement. Verification will require independent replication and unbiased tests at multiple scales in multiple habitats under different human-induced mortality rates, and peer review before the new methods are considered reliable.⍰ (Treves & Santiago-Ã⍰vila, 2023)
Carrie Rosenblatt	N	Jan182023	19:11:13	Wisconsin Department of Natural Resources Draft 2022 Wolf Management Plan	Dear Sirs/Madams, Regarding the draft Wolf Management Plan: the plan contains improvements compared to previous versions, however, it is far from reflecting the best available science, ethics and broad public values that should guide wolf policy and coexistence. I support increasing protections for wolves, requiring only non-lethal conflict interventions and totally banning recreational killing of these sentient, intelligent animals who are important for the ecosystem! What we like: We appreciate the efforts of all WDNR staff involved in updating the state's wolf management plan. Although we believe the current plan needs significant updating (see next section), we recognize the efforts and improvements made to the previous plan, including: ●⍰ Wolves in WI will no longer be managed by reference to the old numerical goal of 350 wolves. ●⍰ There is much greater recognition of the ecological role of wolves ●⍰ The inclusion of a social survey, which notes increased positive views of wolves, knowledge of their ecological roles and increased opposition to the motives and methods for killing wolves ●⍰ The adoption of proposed buffer zones around tribal reservations (i.e., previously no buffer zones existed) What we don't like: ●⍰ The current draft does not reflect the best available science, and is missing a substantial amount of scientific literature on (see reference list below): ● wolf ethology, sentience, sapience, sociability, agency and wellbeing ● effectiveness of non-lethal interventions, especially relative to lethal ones ● the impact of widespread killing on wolves' physiology, behavior, wellbeing, social dynamics, ecological relationships and evolution The above scientific omissions, combined with the emphasis on and promotion of sustainable recreational killing and consumptive users as a main management strategy, results

Carol E Fletcher	Unknown	Jan182023	22:02:24	wolf management plan	Dear Sirs and/or Madams, I would like to congratulate you for proposing changes to the current wolf management program. Your recognition that wolves need to be managed recognizing the role they play in the ecosystem as a whole, rather than by an arbitrary target number, is an important step forward. I also thank you for partially recognizing the changing views of society as a whole toward wolves (they are not just the big bad creatures of fairytales) and respecting tribal values by creating buffer zones around tribal land. That being said, there are still a significant number of improvements needed in the plan. Because you do not cite any of the numerous credible studies regarding wolves that already exist, the plan is able to ignore best practices as currently known. For example: 1.) wolves are highly social animals with family structures important to their well being and management. 2.) The effectiveness of non-lethal interventions is ignored. 3.) Hunting with hounds is a barbaric practice that is no longer supported by most of modern society. 4.) The plan downplays the lack of support for hunting wolves by the majority of the general public. 5.) The plan is particularly insulting to indigenous people by ignoring their feelings and beliefs about wolves including that they should never be killed. 6.) Instead of making abatement measures a priority, they are ignored by the plan. In sum the plan, as currently proposed, continues the use of outdated practices rather than basing the proposal upon current understanding of science and public attitudes. As a result it badly short changes the general public, indigenous peoples, and most importantly, wolves. I thank you in advance for thoughtfully considering my comments. Carol E Fletcher
vicky tang	Unknown	Jan182023	23:41:38	Protect Wolves in Wisconsin	What we like: We appreciate the efforts of all WDNR staff involved in updating the state's wolf management plan. Although we believe the current plan needs significant updating (see next section), we recognize the efforts and improvements made to the previous plan, including: ● Wolves in WI will no longer be managed by reference to the old numerical goal of 350 wolves. ● There is much greater recognition of the ecological role of wolves ● The inclusion of a social survey, which notes increased positive views of wolves, knowledge of their ecological roles and increased opposition to the motives and methods for killing wolves ● The adoption of proposed buffer zones around tribal reservations (i.e., previously no buffer zones existed) What we don't like: ● The current draft does not reflect the best available science, and is missing a substantial amount of scientific literature on (see reference list below): ○ wolf ethology, sentience, sapience, sociability, agency and wellbeing ○ effectiveness of non-lethal interventions, especially relative to lethal ones ○ the impact of widespread killing on wolves' physiology, behavior, wellbeing, social dynamics, ecological relationships and evolution ● The above scientific omissions, combined with the emphasis on and promotion of sustainable recreational killing and consumptive users as a main management strategy, results in a biased plan that runs contrary to scientific evidence despite much of this omitted scientific evidence being more recent, numerous and of stronger inference. ● The plan should strictly curtail any lethal management of wolves except in extremely rare circumstances of immediate defense of life. ○ A substantial body of research documenting human-caused mortality in North American wolves, including Wisconsin wolves, has found that policies allowing liberalized killing of wolves result in a direct increase in the hazard and incidence of illegal killings.
	Unknown	Jan192023	0:50:35	Wolf Management Plan Comments	Dear Sir/Madam, Whilst the current plan needs significant updating, will I will comment on later in this message, I do recognise the efforts and improvements made to the previous plan, including: ●⍰ Wolves in WI will no longer be managed by reference to the old numerical goal of 350 wolves. ●⍰ There is much greater recognition of the ecological role of wolves. ●⍰ The inclusion of a social survey, which notes increased positive views of wolves,knowledge of their ecological roles and increased opposition to the motives and methods for killing wolves. ●⍰

					The adoption of proposed buffer zones around tribal reservations (i.e., previously no buffer zones existed). Now for my comments on the required improvement: ●⍰ The current draft does not reflect the best available science, and is missing a substantial amount of scientific literature on: ● wolf ethology, sentience, sapience, sociability, agency and wellbeing; ● effectiveness of non-lethal interventions, especially relative to lethal ones; ● the impact of widespread killing on wolves' physiology, behaviour, wellbeing,social dynamics, ecological relationships and evolution. ●⍰ The above scientific omissions, combined with the emphasis on and promotion of sustainable recreational killing and consumptive users as a main management strategy,results in a biased plan that runs contrary to scientific evidence despite much of this omitted scientific evidence being more recent, numerous and of stronger inference. ●⍰ The plan should curtail strictly any lethal management of wolves except in extremely rare circumstances of immediate defence of life. ● A substantial body of research documenting human-caused mortality in North American wolves, including Wisconsin wolves, has found that policies allowing liberalised killing of wolves result in a direct increase in the hazard and incidence of illegal killings. ● Hounding or hound training, which are akin to allowing legalised dog fighting,should be illegal or severely restricted as this practice is extremely cruel to wolves and hounds alike and is not supported by the majority of hunters or the broad public. ●⍰ The plan should prioritise wolf protections and concentrate solely on non-lethal management of wolves in response to livestock conflicts to ensure ethical coexistence. ● Despite Act 169, which mandates a wolf hunting season, the department can still restrict the implementation of lethal methods by setting minimal quotas, including a quota of '0' wolves, restricting timing and methods. ● Several studies have proven a proactive non-lethal approach leads to better conflict mitigation. ● Lethal management often fails to provide a long-term solution to wolf predation and has the least consistent success rates when compared to non-lethal practices. In addition, there is significant evidence showing that lethal wolf management may be less functionally effective at mitigating subsequent livestock losses than non-lethal deterrents. ●⍰ The plan should require the implementation of abatement measures as well as the use of non-lethal conflict minimisation techniques by domestic animal owners for the latter to receive compensation for confirmed predation. ●⍰ The plan also runs contrary to public values towards wolves (and omits mention of such majority values from the plan), despite department surveys evidencing that the broad public cares about wolves as individuals (and not just for the viability of the population). Given the recent liberalisation of killing wolves by the state, it would be incredibly informative to note majority support of the following reasons for opposing a regulated wolf hunting/trapping season (which are all omitted from the plan): opposition to specific methods of harvest like hounds (64%) or traps (70%), feelings that hunting wolves is unnecessary (62%) or culturally offensive to Native American tribes (57%). ● All such reasons convey majority disagreement with practices currently promoted and endorsed by the legislature and the WDNR, and such a conflict between managers and the public should not only be acknowledged, but foregrounded and carefully considered in policy (instead of dismissed). ● Such decisions to omit literature or downplay evidence (e.g., such as majority opposition to killing wolves and their reasons) are contrary to principles of scientific integrity (e.g., present all relevant scientific evidence to the public) as well as ethics (e.g., disguising ethical decisions, such as recreational wolf killing, as robustly supported by science). ●⍰ Conflicting agency objectives (e.g., optimising public hunting and conflict mitigation) are not only not acknowledged, but even misunderstood as harmonious, against the body of scientific evidence. That culminates in the prioritisation of consumptive values and policies; e.g., according to the body of scientific literature, use of lethal methods, and two especially public hunts, are contrary to most objectives relevant to: harm mitigation, the wellbeing of wolves, their ecological roles, and their non-exploitative enjoyment (i.e., Objectives A, B, D and F). ●⍰ There is a stark lack of consideration for individual wolves, wolf population health(including wellbeing), and measurable indicators for assessing any harms barring disease prevalence (e.g., accounting for cortisol levels or other stress hormones, measures of pair/pack persistence) ●⍰ There is an inappropriate understanding and consideration of tribal worldviews about wolves. Tribal worldviews of wolves are misconstrued as 'cultural benefits' tribes receive from the existence of a wolf population, when in fact tribal worldviews consider each individual wolf as a person and relative. Cultural respect and sensitivity towards such views, shared by many non-tribal members, demand the strict mitigation of lethalmeasures, especially recreational killing, as opposed to their current promotion in theplan. ●⍰ In general, all omissions of scientific literature, the arbitrary prioritisation of policy objectives, the rhetoric of the plan and the dismissal of public values and concerns for wolves point towards a biased, unscientific and instrumental view of wolves that promotes values contrary to broad public perspectives on wolves. ●⍰ 'SOM' wolf estimation methodology “ From a recent critique: The new methods sacrifice precision, but are believed to retain adequate accuracy and sensitivity to changing conditions for reliable decision-making. We review evidence for the accuracy, precision, and sensitivity of the new 'scaled occupancy model' (SOM) applied in Wisconsin. We conclude that the Wisconsin method would systematically overestimate wolf abundance by large (but currently incalculable) margins. Because Wisconsin, similar to other states, not only changed to unverified methods but also implemented widespread wolf killing, shortcomings in their estimates of wolf abundance may have far-reaching consequences for population viability and confidence in state wildlife managers. We discuss findings from Wisconsin alongside similar findings for other states' occupancy models being insensitive to human causes of mortality that have recently increased. Overall, Wisconsin's proposed method for estimating wolf abundance shows significant departures from best practices in scientific measurement. Verification will require independent replication and unbiased tests at multiple scales in multiple habitats under different human-induced mortality rates, and peer review before the new methods are considered reliable.⍰ (Treves & Santiago-Ã⍰vila, 2023) Below is the list of studies not integrated into the current draft wolf plan. Angel (Maurene) Conway	Unknown	Jan192023	2:06:38	state's wolf management plan	What we like: We appreciate the efforts of all WDNR staff involved in updating the state's wolf management plan. Although we believe the current plan needs significant updating (see next section), we recognize the efforts and improvements made to the previous plan, including: ●⍰ Wolves in WI will no longer be managed by reference to the old numerical goal of 350 wolves. ●⍰ There is much greater recognition of the ecological role of wolves ●⍰ The inclusion of a social survey, which notes increased positive views of wolves, knowledge of their ecological roles and increased opposition to the motives and methods for killing wolves ●⍰ The adoption of proposed buffer zones around tribal reservations (i.e., previously no buffer zones existed) What we don't like: ●⍰ The current draft does not reflect the best available science, and is missing a substantial amount of scientific literature on (see reference list below): ● wolf ethology, sentience, sapience, sociability, agency and wellbeing ● effectiveness of non-lethal interventions, especially relative to lethal ones ● the impact of widespread killing on wolves' physiology, behavior, wellbeing, social dynamics, ecological relationships and evolution ●⍰ The above scientific omissions, combined with the emphasis on and promotion of sustainable recreational killing and consumptive users as a main management strategy, results in a biased plan that runs contrary to scientific evidence despite much of this omitted scientific evidence being more recent, numerous and of stronger inference. ●⍰ The plan should strictly curtail any lethal management of wolves except in extremely rare circumstances of immediate defense of life. ● A substantial body of research documenting human-caused mortality in North American wolves, including Wisconsin wolves, has found that policies allowing liberalized killing of wolves result in a direct increase in the hazard and incidence of illegal killings. ● Hounding or hound training, which are akin to allowing legalized dogfighting, should be illegal or severely restricted as this practice is extremely cruel to wolves and hounds alike and is not supported by the majority of hunters or the broad public. ●⍰ The plan should prioritize wolf protections and concentrate solely on non-lethal management of wolves in response to livestock conflicts to ensure ethical coexistence. ● Despite Act 169, which mandates a wolf hunting season, the department can still restrict the implementation of lethal methods by setting minimal quotas, including a quota of '0' wolves, restricting timing and methods. ● Several studies have proven a proactive non-lethal approach leads to better conflict mitigation. ● Lethal management often fails to provide a long-term solution to wolf predation and has the least consistent success rates when compared to non-lethal practices. In addition, there is significant evidence showing that lethal wolf management may be less functionally effective at mitigating subsequent livestock losses than non-lethal deterrents. ●⍰ The plan should require the implementation of abatement measures as well as the use of non-lethal conflict minimization techniques by domestic animal owners for the latter to receive compensation for confirmed predation. ●⍰ The plan also runs contrary to public values towards wolves (and omits mention of such majority values from the plan), despite department surveys evidencing that the broad public cares about wolves as individuals (and not just for the viability of the population). Given the recent liberalization of killing wolves by the state, it would be incredibly informative to note majority support of the following reasons for opposing a regulated wolf hunting/trapping season (which are all omitted from the plan): opposition to specific methods of harvest like hounds (64%) or traps (70%), feelings that hunting wolves is unnecessary (62%) or culturally offensive to Native American tribes (57%). ● All such reasons convey majority disagreement with practices currently promoted and endorsed by the legislature and the WDNR, and such a conflict between managers and the public should not only be acknowledged, but foregrounded and carefully considered in policy (instead of dismissed). ● Such decisions to omit literature or downplay evidence (e.g., such as majority opposition to killing wolves and their reasons) are contrary to principles of scientific integrity (e.g., present all relevant scientific evidence to the public) as well as ethics (e.g., disguising ethical decisions, such as recreational wolf killing, as robustly supported by science). ●⍰ Conflicting agency objectives (e.g., optimizing public hunting and conflict mitigation) are not only not acknowledged, but even misunderstood as harmonious, against the body of scientific evidence. That culminates in the prioritization of consumptive values and policies; e.g., according to the body of scientific literature, use of lethal methods, and 2 especially public hunts, are contrary to most objectives relevant to: harm mitigation, the wellbeing of wolves, their ecological roles, and their non-exploitative enjoyment (i.e., Objectives A, B, D and F). ●⍰ There is a stark lack of consideration for individual wolves, wolf population health (including wellbeing), and measurable indicators for assessing any harms barring disease prevalence (e.g., accounting for cortisol levels or other stress hormones, measures of pair/pack persistence) ●⍰ There is an inappropriate understanding and consideration of tribal worldviews about wolves. Tribal worldviews of wolves are misconstrued as 'cultural benefits' tribes receive from the existence of a wolf population, when in fact tribal worldviews consider each individual wolf as a person and relative. Cultural respect and sensitivity towards such views, shared by many non-tribal members, demand the strict mitigation of lethal measures, especially recreational killing, as opposed to their current promotion in the plan. ●⍰ In general, all omissions of scientific literature, the arbitrary prioritization of policy objectives, the rhetoric of the plan and the dismissal of public values and concerns for wolves point towards a biased, unscientific and instrumental view of wolves that promotes values contrary to broad public perspectives on wolves. ●⍰ 'SOM' wolf estimation methodology “ From a recent critique: The new methods sacrifice precision, but are believed to retain adequate accuracy and sensitivity to changing conditions for reliable decision-making. We review evidence for the accuracy, precision, and sensitivity of the new 'scaled occupancy model' (SOM) applied in Wisconsin. We conclude that the Wisconsin method would systematically overestimate wolf abundance by large (but currently incalculable) margins. Because Wisconsin, similar to other states, not only changed to unverified methods but also implemented widespread wolf killing, shortcomings in their estimates of wolf abundance may have far-reaching consequences for population viability and confidence in state wildlife managers. We discuss findings from Wisconsin alongside similar findings for other states' occupancy models being insensitive to human causes of mortality that have recently increased. Overall, Wisconsin's proposed method for estimating wolf abundance shows significant departures from best practices in scientific measurement. Verification will require independent replication and unbiased tests at multiple scales in multiple habitats under different human-induced mortality rates, and peer review before the new methods are considered reliable.⍰ (Treves & Santiago-Ã⍰vila, 2023) Angel Conway Ph. [redacted]

Hounding or hound training, which are akin to allowing legalized dogfighting, should be illegal or severely restricted as this practice is extremely cruel to wolves and hounds alike and is not supported by the majority of hunters or the broad public. ●⍰ The plan should prioritize wolf protections and concentrate solely on non-lethal management of wolves in response to livestock conflicts to ensure ethical coexistence. ● Despite Act 169, which mandates a wolf hunting season, the department can still restrict the implementation of lethal methods by setting minimal quotas, including a quota of '0' wolves, restricting timing and methods. ● Several studies have proven a proactive non-lethal approach leads to better conflict mitigation. ● Lethal management often fails to provide a long-term solution to wolf predation and has the least consistent success rates when compared to non-lethal practices. In addition, there is significant evidence showing that lethal wolf management may be less functionally effective at mitigating subsequent livestock losses than non-lethal deterrents. ●⍰ The plan should require the implementation of abatement measures as well as the use of non-lethal conflict minimization techniques by domestic animal owners for the latter to receive compensation for confirmed predation. ●⍰ The plan also runs contrary to public values towards wolves (and omits mention of such majority values from the plan), despite department surveys evidencing that the broad public cares about wolves as individuals (and not just for the viability of the population). Given the recent liberalization of killing wolves by the state, it would be incredibly informative to note majority support of the following reasons for opposing a regulated wolf hunting/trapping season (which are all omitted from the plan): opposition to specific methods of harvest like hounds (64%) or traps (70%), feelings that hunting wolves is unnecessary (62%) or culturally offensive to Native American tribes (57%). ● All such reasons convey majority disagreement with practices currently promoted and endorsed by the legislature and the WDNR, and such a conflict between managers and the public should not only be acknowledged, but foregrounded and carefully considered in policy (instead of dismissed). ● Such decisions to omit literature or downplay evidence (e.g., such as majority opposition to killing wolves and their reasons) are contrary to principles of scientific integrity (e.g., present all relevant scientific evidence to the public) as well as ethics (e.g., disguising ethical decisions, such as recreational wolf killing, as robustly supported by science). ●⍰ Conflicting agency objectives (e.g., optimizing public hunting and conflict mitigation) are not only not acknowledged, but even misunderstood as harmonious, against the body of scientific evidence. That culminates in the prioritization of consumptive values and policies; e.g., according to the body of scientific literature, use of lethal methods, and. especially public hunts, are contrary to most objectives relevant to: harm mitigation, the wellbeing of wolves, their ecological roles, and their non-exploitative enjoyment (i.e., Objectives A, B, D and F). ●⍰ There is a stark lack of consideration for individual wolves, wolf population health (including wellbeing), and measurable indicators for assessing any harms barring disease prevalence (e.g., accounting for cortisol levels or other stress hormones, measures of pair/pack persistence) ●⍰ There is an inappropriate understanding and consideration of tribal worldviews about wolves. Tribal worldviews of wolves are misconstrued as 'cultural benefits' tribes receive from the existence of a wolf population, when in fact tribal worldviews consider each individual

Name	Resident	Date	Time	Subject	Email Body
					wolf as a person and relative. Cultural respect and sensitivity towards such views, shared by many non-tribal members, demand the strict mitigation of lethal measures, especially recreational killing, as opposed to their current promotion in the plan. ● In general, all omissions of scientific literature, the arbitrary prioritization of policy objectives, the rhetoric of the plan and the dismissal of public values and concerns for wolves point towards a biased, unscientific and instrumental view of wolves that promotes values contrary to broad public perspectives on wolves. ● 'SOM' wolf estimation methodology " From a recent critique: The new methods sacrifice precision, but are believed to retain adequate accuracy and sensitivity to changing conditions for reliable decision-making. We review evidence for the accuracy, precision, and sensitivity of the new 'scaled occupancy model' (SOM) applied in Wisconsin. We conclude that the Wisconsin method would systematically overestimate wolf abundance by large (but currently incalculable) margins. Because Wisconsin, similar to other states, not only changed to unverified methods but also implemented widespread wolf killing, shortcomings in their estimates of wolf abundance may have far-reaching consequences for population viability and confidence in state wildlife managers. We discuss findings from Wisconsin alongside similar findings for other states' occupancy models being insensitive to human causes of mortality that have recently increased. Overall, Wisconsin's proposed method for estimating wolf abundance shows significant departures from best practices in scientific measurement. Verification will require independent replication and unbiased tests at multiple scales in multiple habitats under different human-induced mortality rates, and peer review before the new methods are considered reliable. (Treves & Santiago-Ãvila, 2023) Sincerely, Seth Coffey
Jennifer Valentine	Unknown	Jan192023	15:33:09	Wolf Management Plan Comments	● The current draft does not reflect the best available science, and is missing a substantial amount of scientific literature on (see reference list below): ● wolf ethology, sentience, sapience, sociability, agency and wellbeing ● effectiveness of non-lethal interventions, especially relative to lethal ones ● the impact of widespread killing on wolves' physiology, behavior, wellbeing, social dynamics, ecological relationships and evolution ● The above scientific omissions, combined with the emphasis on and promotion of sustainable recreational killing and consumptive users as a main management strategy, results in a biased plan that runs contrary to scientific evidence despite much of this omitted scientific evidence being more recent, numerous and of stronger inference. ● The plan should strictly curtail any lethal management of wolves except in extremely rare circumstances of immediate defense of life. ● A substantial body of research documenting human-caused mortality in North American wolves, including Wisconsin wolves, has found that policies allowing liberalized killing of wolves result in a direct increase in the hazard and incidence of illegal killings. ● Hounding or hound training, which are akin to allowing legalized dogfighting, should be illegal or severely restricted as this practice is extremely cruel to wolves and hounds alike and is not supported by the majority of hunters or the broad public. ● The plan should prioritize wolf protections and concentrate solely on non-lethal management of wolves in response to livestock conflicts to ensure ethical coexistence. ● Despite Act 169, which mandates a wolf hunting season, the department can still restrict the implementation of lethal methods by setting minimal quotas, including a quota of '0' wolves, restricting timing and methods. ● Several studies have proven a proactive non-lethal approach leads to better conflict mitigation. ● Lethal management often fails to provide a long-term solution to wolf predation and has the least consistent success rates when compared to non-lethal practices. Dr. Kellen Dunn	Unknown	Jan192023	16:38:26	Wolf Management Plans in Wisconsin - PROTECT ESSENTIAL WOLVES!	Dear Officials, As a Wisconsin resident, I strongly urge you to PROTECT our precious, iconic and ESSENTIAL wildlife especially WOLVES at all costs. It is time to co-exist with wildlife and always use non-legal methods. Nature always balances itself and there is no need for human intervention. Humans generally mess things up and create imbalances in the ecosystem long term. We manage⍰ wildlife by leaving them alone (free from human harm or intervention) and protect their habitat so that they have enough room to live. It is time to prioritize wildlife, NOT greedy ranchers or vile trophy hunters. I am in favor of increasing wolf protections, requiring non-lethal conflict interventions, and banning recreational killing. What we like: We appreciate the efforts of all WDNR staff involved in updating the state's wolf management plan. Although we believe the current plan needs significant updating (see next section), we recognize the efforts and improvements made to the previous plan, including: ●⍰ Wolves in WI will no longer be managed by reference to the old numerical goal of 350 wolves. ●⍰ There is much greater recognition of the ecological role of wolves ●⍰ The inclusion of a social survey, which notes increased positive views of wolves, knowledge of their ecological roles and increased opposition to the motives and methods for killing wolves ●⍰ The adoption of proposed buffer zones around tribal reservations (i.e., previously no buffer zones existed) What we don't like: ●⍰ The current draft does not reflect the best available science, and is missing a substantial amount of scientific literature on (see reference list below): ● wolf ethology, sentience, sapience, sociability, agency and wellbeing ● effectiveness of non-lethal interventions, especially relative to lethal ones ● the impact of widespread killing on wolves' physiology, behavior, wellbeing, social dynamics, ecological relationships and evolution ●⍰ The above scientific omissions, combined with the emphasis on and promotion of sustainable recreational killing and consumptive users as a main management strategy, results in a biased plan that runs contrary to scientific evidence despite much of this omitted scientific evidence being more recent, numerous and of stronger inference. ●⍰ The plan should strictly curtail any lethal management of wolves except in extremely rare circumstances of immediate defense of life. ● A substantial body of research documenting human-caused mortality in North American wolves, including Wisconsin wolves, has found that policies allowing liberalized killing of wolves result in a direct increase in the hazard and incidence of illegal killings. ● Hounding or hound training, which are akin to allowing legalized dogfighting, should be illegal or severely restricted as this practice is extremely cruel to wolves and hounds alike and is not supported by the majority of hunters or the broad public. ●⍰ The plan should prioritize wolf protections and concentrate solely on non-lethal management of wolves in response to livestock conflicts to ensure ethical coexistence. ● Despite Act 169, which mandates a wolf hunting season, the department can still restrict the implementation of lethal methods by setting minimal quotas, including a quota of '0' wolves, restricting timing and methods. ● Several studies have proven a proactive non-lethal approach leads to better conflict mitigation. ● Lethal management often fails to provide a long-term solution to wolf predation and has the least consistent success rates when compared to non-lethal practices. In addition, there is significant evidence showing that lethal wolf management may be less functionally effective at mitigating subsequent livestock losses than non-lethal deterrents. ●⍰ The plan should require the implementation of abatement measures as well as the use of non-lethal conflict minimization techniques by domestic animal owners for the latter to receive compensation for confirmed predation. ●⍰ The plan also runs contrary to public values towards wolves (and omits mention of such majority values from the plan), despite department surveys evidencing that the broad public cares about wolves as individuals (and not just for the viability of the population). Given the recent liberalization of killing wolves by the state, it would be incredibly informative to note majority support of the following reasons for opposing a regulated wolf hunting/trapping season (which are all omitted from the plan): opposition to specific methods of harvest like hounds (64%) or traps (70%), feelings that hunting wolves is unnecessary (62%) or culturally offensive to Native American tribes (57%). ● All such reasons convey majority disagreement with practices currently promoted and endorsed by the legislature and the WDNR, and such a conflict between managers and the public should not only be acknowledged, but foregrounded and carefully considered in policy (instead of dismissed). ● Such decisions to omit literature or downplay evidence (e.g., such as majority opposition to killing wolves and their reasons) are contrary to principles of scientific integrity (e.g., present all relevant scientific evidence to the public) as well as ethics (e.g., disguising ethical decisions, such as recreational wolf killing, as robustly supported by science). ●⍰ Conflicting agency objectives (e.g., optimizing public hunting and conflict mitigation) are not only not acknowledged, but even misunderstood as harmonious, against the body of scientific evidence. That culminates in the prioritization of consumptive values and policies; e.g., according to the body of scientific literature, use of lethal methods, and 2 especially public hunts, are contrary to most objectives relevant to: harm mitigation, the wellbeing of wolves, their ecological roles, and their non-exploitative enjoyment (i.e., Objectives A, B, D and F). ●⍰ There is a stark lack of consideration for individual wolves, wolf population health (including wellbeing), and measurable indicators for assessing any harms barring disease prevalence (e.g., accounting for cortisol levels or other stress hormones, measures of pair/pack persistence) ●⍰ There is an inappropriate understanding and consideration of tribal worldviews about wolves. Tribal worldviews of wolves are

Overall, Wisconsin's proposed method for estimating wolf abundance shows significant departures from best practices in scientific measurement. Verification will require independent replication and unbiased tests at multiple scales in multiple habitats under different human-induced mortality rates, and peer review before the new methods are considered reliable.□ (Treves & Santiago-Ã□vila, 2023) Rating: 4 Kind regards, Dr. Kellen Dunn
Brenda & Andy	Y	Jan192023	20:42:00	Wolf Management	I am a Wisconsin resident and have been hunting in Wisconsin for 50 years. I have attended many spring fish and game hearings and have written the DNR a number of times regarding deer hunting and CWD. I received one reply from the DNR that stated that deer were the property of the DNR to sell doe tags which I found out later that deer are the property of Wisconsin residents to be managed by the DNR. (a subtle difference but very important) I am writing today to express concern about the DNR's wolf management and hunting in our great state. I want to share three concerns with Wisconsin wolf management: Number one: how can a wolf Management plan be developed and presented to us with no population goal? Without a population goal, how can a harvest quota be set by the DNR? Number two: if there is a healthy wolf population in Wisconsin, the DNR gives an over-winter wolf count of 800 to 1200 wolves. How and why is it not possible to give Wisconsin residents a realistic and sensible wolf population goal for Wisconsin? I believe the wolf is similar to bears as predators. The Wisconsin DNR sets population and harvest goals for bears. Why are wolves being managed differently? Please manage Wisconsin wolves like you do Wisconsin bears! Number three: I think Wisconsin sportsmen and women should be offered the opportunity to harvest the wolf based on scientific management. Wisconsin sportsmen and women pay the majority of the DNR's budget and should be a main factor on how wolves are managed. It appears that there is a political opinion being voiced and listened to that wants the wolf population to continue to grow. (To what extent?) Is the DNR using sportsmen and women's money to pay damage claims and how high can the dollar amount grow to? When does this end? Wolves are a valuable predator and resource for all Wisconsin residents but the DNR should manage wolves just like they do bears, a valuable resource. Let's hope the DNR takes the lead in wolf management. Sincerely, Andy Armour Germantown

Nedim C Buyukmihci	N	Jan202023	10:26:21	Wolf Management Plan Comments	20 January 2023 Wolf Management Plan Comments 101 S. Webster Street PO Box 7921 Madison, WI 53707-7921 Re: Wisconsin Wolf Management Plan 2022 I am a veterinarian and Emeritus Professor of Veterinary Medicine at the University of California, with several decades of experience. What I write here is my professional opinion. I am offering my perspective on the issue of gray wolf "management". The 2022-11-09 draft ("Wisconsin Wolf Management Plan 2022") appears to be a reasonably thorough review of the various issues. My concern arises from words like "management" and "harvest". The former implies knowledge that may be illusory in nature, the latter treats the wolves as if they are some sort of agricultural product, as if they have been planted as "crops" like corn or wheat to be gathered when ready. Rather than use euphemisms that soften or obfuscate the issue, the Plan should be open and honest: kill is the correct word in this case. I am aware that some of my references are already in your "Literature Cited" section and some of what I state may be redundant in that regard. In addition, in order to illustrate and amplify the general biological principles I mention, I refer to published work involving non-canid species. People may claim that wolves are responsible for killing large numbers of 'livestock' such as cattle or sheep. Further, it may be claimed that wolves 'compete' with human hunters for animals such as antelope, elk or moose, and cause a reduction in the populations of these animals, the belief being that wolf control will lead to increased numbers of these (and other) animals for hunting. There are no data that conclusively support this assumption. With 'livestock', it has been shown that killing wolves results in more wolf-related killing of 'livestock' in the years that follow (Wielgus et al 2015). With moose, there is a complex relationship between wolves and moose populations, with availability of food for moose, not the presence of wolves, an important factor in determining population stability (Peterson et al 1984). In the case of antelope and deer, a vibrant wolf population increases their numbers because it reduces the population of coyotes whose predation of recently born offspring is responsible for reducing herd sizes (Berger & Conner 2008; Berger et al 2008). As with all situations with wildlife, our interference, in this case the killing off of large predators such as wolves, results in unintended and negative results with respect to other animals and biodiversity (Berger & Conner 2008). One such example involves Scotland, where people killed off the wolves resulting in red deer 'overpopulation'. Because this unnatural increase in deer numbers began causing 'problems', the Scots proposed to reintroduce the wolves as a solution (Anon 2009). If population 'control' is deemed necessary, only non-lethal methods of control should be used. These have been shown to be effective (Seal 1991; Tavss 2005). Nevertheless, given our appalling history of creating problems by "wildlife management", the notion of control should be carefully re-considered, particularly if either large-scale killing or other interference is to be implemented. It is axiomatic that in nature, there is no such thing as "overpopulation". Numbers of a particular species wax and wane naturally, coinciding and complementing similar cycles with other species and are even "controlled" by complex predator-prey relationships (Berger & Conner 2008; Hudson et al 1992; Peterson et al 1984). We are usually extremely short-sighted in our perceptions and mistakenly think that lethal "control" of these populations is the only answer. In our zeal to manipulate these populations in general, including the introduction of "desirable" species, we usually cause unintended and often disastrous consequences (Anon 2009; Farrer et al 2011; Gumbrell 1986; Hutchins et al 1982; Invasive Species Specialist Group 2007; Jessup et al 1986; Stevenson 1983; West & Rudd 1983). Often the species in question increases in numbers due to the reproductive pressure caused by the unnatural scale of killing or other species are negatively impacted by the situation. We need to also consider that the wolves have just as much natural "right" to occupy the land in question. Given that we are responsible for the decimation and near extinction of wolves, we owe them a particular debt. An animal's (species') perceived value to us, or our fear of it, should not be what determines if the species should be protected fully; in this respect, using the word "protection" is meaningless if killing " eg "harvest" " is allowed. Moreover, we often greatly exaggerate the threat some wildlife species may represent to us (Creel & Rotella 2010; Herrero et al 2011; Ryll 2006). It is not within our wisdom to know what is truly "good" or "bad" when it comes to wildlife. We must accept that all animals belong on this earth and that it is our responsibility to ensure their survival when we are the ones threatening it. Those making decisions about wolf "management" should carefully consider underlying motives. Relevant to this is the following perspective from a group of wildlife managers critical of current practices: "Wildlife science per se can rarely demonstrate that any decision leading to a management objective, such as decreasing a deer population, or to a management action, such as hunting animals, is a biological or ecological necessity. ... Similarly, the decision to harvest a portion of a wildlife population is a reflection of a value position, a conclusion based partly on scientific evidence and efficacy of known alternatives and partly on particular beliefs about the appropriateness of certain human uses of wild animals... "If a professional wildlife manager suggests that a decision is based solely on scientifically-derived biological considerations, the manager either misunderstands the nature of science (by confusing scientific judgements with ethical judgements) (Underwood and Porter 1991) or is deliberately trying to disguise or complement a value judgement under the veil of the legitimacy of science." (Decker et al 1991) It is my hope that you will provide unreserved protection for the wolves of Wisconsin. "Management" should be limited to public education and

					compensation when it is unequivocal that wolves have impacted negatively on a person's livelihood. The land comprising Wisconsin is habitat that "belongs" to the wolves as much as to anyone else. We share “ not own “ this earth with other wildlife, including wolves. Our own sense of compassion, fairness and intellect demand that we learn to live with these individuals. gary thoms	Unknown	Jan202023	10:45:26	Wolfs	I would like you to protect all wildlife to the Max. The endangered species is a no brainer.
Debbie Wall	N	Jan202023	19:40:46	Re: Wolf management plan	Since we've put a man on the moon, the human population has more than doubled while that of the wild animal nations has more than halved. The survivors deserve protection and to live and raise their families in peace. This includes wolves. Any management should be based on science and not emotion or long held prejudice. Lethal control should never be the default. We need to adopt peaceful coexistence and compassionate conservation strategies. Thank-you, Debbie Wall & The Gang of Fur Winnipeg, Manitoba Canada
Tracey Bonner	N	Jan212023	9:06:17	Gray Wolves Wisconsin	Good morning, I have traveled to your great State and although I did not have the pleasure of spotting one of your Gray Wolves in the wild , I would have like to have been blessed with a viewing.. Gray Wolves belong here and are a part of our United States heritage where they should have a place free from the harassment and killings that human beings inflict upon them. Gray Wolves are not these evil monsters that some residents, who are either ignorant or uninformed, are portraying them as. Gray Wolves are magnificently intelligent, family oriented animals who mate for life. There is absolutely no reason to eradicate these magnificent animals. There are many non-lethal ways to deter Gray Wolves, such as fencing, predator control deterrent lights and livestock protection dogs, just to name a few. Thank for allowing me to speak on behalf of our Gray Wolves. Tracey from Texas
Su Libby	Y	Jan212023	9:09:48	Wisconsin Wolf Management Plan	25 years of fighting for a well reasoned logical plan for managing Wolves in Wisconsin has left us bewildered. From the very beginning, starting with the politically motivated lowering of Biological carrying capacity opinion (professional Wildlife Biologists who were consulted by the WDNR in the early 2000's gave informed estimates of 850 animals) , the number of wolves allowed to stay alive was lowered by a bunch of know nothing politicians to the Holy Mantra of 350 animals, based on nothing but propaganda and repetition ,repetition and repetition by George Meyer and his cronies at the Wisconsin Wildlife Federation and the Wisconsin Bear Hunter's Association. Professional Wildlife Biologists were ignored. Tribal voices were ignored, and Most National and State Environmental and Humane Organizations were quickly eliminated from the equation. We sat in in many of those meetings from 2000 through 2017 and later became several of many Wisconsin residents HORRIFIED at the planned rapid extermination of Wolves euphemistically referred to as a HUNT where several of the hunting zones reached and then exceeded their legal quotas in a blazingly short amount of time. Turns out all many of the " Hunter's" who complained about how elusive wolves were and how difficult they were to find, most likely knew where they were all along with the help of some retired DNR Warden's such as the one from Bayfield. Again, we implore any level headed and professional DNR Staffers to not allow themselves to be influenced by this Lobby of extreme trophy Hunter's. Base the new wolf policy on input from all the Stakeholders. Tribes, Environmental Organizations, Citizens, Politicians. ..and Hunter's. Sincerely Su Libby Jo Bailey Great Old Broads for Wilderness [redacted] Bayfield, WI
Sandra Couch	Unknown	Jan212023	12:19:00	PROTECT WOLVES	What we like: We appreciate the efforts of all WDNR staff involved in updating the state's wolf management plan. Although we believe the current plan needs significant updating (see next section), we recognize the efforts and improvements made to the previous plan, including: ● Wolves in WI will no longer be managed by reference to the old numerical goal of 350 wolves. ● There is much greater recognition of the ecological role of wolves ● The inclusion of a social survey, which notes increased positive views of wolves, knowledge of their ecological roles and increased opposition to the motives and methods for killing wolves ● The adoption of proposed buffer zones around tribal reservations (i.e., previously no buffer zones existed) What we don't like: The current draft does not reflect the best available science, and is missing a substantial amount of scientific literature on (see reference list below): ● wolf ethology, sentience, sapience, sociability, agency and wellbeing ● effectiveness of non-lethal interventions, especially relative to lethal ones ● the impact of widespread killing on wolves' physiology, behavior, wellbeing, social dynamics, ecological relationships and evolution ● The above scientific omissions, combined with the emphasis on and promotion of sustainable recreational killing and consumptive users as a main management strategy, results in a biased plan that runs contrary to scientific evidence despite much of this omitted scientific evidence being more recent, numerous and of stronger inference. ● The plan should strictly curtail any lethal management of wolves except in extremely rare circumstances of immediate defense of life. ● A substantial body of research documenting human-caused mortality in North American wolves, including Wisconsin wolves, has found that policies allowing liberalized killing of wolves result in a direct increase in the hazard and incidence of illegal killings. ● Hounding or hound training, which are akin to allowing legalized dogfighting, should be illegal or severely restricted as this practice is extremely cruel to wolves and hounds alike and is not supported by the majority of hunters or the broad public. ● The plan should prioritize wolf protections and concentrate solely on non-lethal management of wolves in response to livestock conflicts to ensure ethical coexistence. ● Despite Act 169, which mandates a wolf hunting season, the department can still restrict the implementation of lethal methods by setting minimal quotas, including a quota of '0' wolves, restricting timing and methods. ● Several studies have proven a proactive non-lethal approach leads to better conflict mitigation. ● Lethal management often fails to provide a long-term solution to wolf predation and has the least consistent success rates when compared to non-lethal practices. In addition, there is significant evidence showing that lethal wolf management may be less functionally effective at mitigating subsequent livestock losses than non-lethal deterrents. ● The plan should require the implementation of abatement measures as well as the use of non-lethal conflict minimization techniques by domestic animal owners for the latter to receive compensation for confirmed predation. ● The plan also runs contrary to public values towards wolves (and omits mention of such majority values from the plan), despite department surveys evidencing that the broad public cares about wolves as individuals (and not just for the viability of the population). Given the recent liberalization of killing wolves by the state, it would be incredibly informative to note majority support of the following reasons for opposing a regulated wolf hunting/trapping season (which are all omitted from the plan): opposition to specific methods of harvest like hounds (64%) or traps (70%), feelings that hunting wolves is unnecessary (62%) or culturally offensive to Native American tribes (57%). ● All such reasons convey majority disagreement with practices currently promoted and endorsed by the legislature and the WDNR, and such a conflict between managers and the public should not only be acknowledged, but foregrounded and carefully considered in policy (instead of dismissed). ● Such decisions to omit literature or downplay evidence (e.g., such as majority opposition to killing wolves and their reasons) are contrary to principles of scientific integrity (e.g., present all relevant scientific evidence to the public) as well as ethics (e.g., disguising ethical decisions, such as recreational wolf killing, as robustly supported by science). ● Conflicting agency objectives (e.g., optimizing public hunting and conflict mitigation) are not only not acknowledged, but even misunderstood as harmonious, against the body of scientific evidence. That culminates in the prioritization of consumptive values and policies; e.g., according to the body of scientific literature, use of lethal methods, and 2 especially public hunts, are contrary to most objectives relevant to: harm mitigation, the wellbeing of wolves, their ecological roles, and their non-exploitative enjoyment (i.e., Objectives A, B, D and F). ● There is a stark lack of consideration for individual wolves, wolf population health (including wellbeing), and measurable indicators for assessing any harms barring disease prevalence (e.g., accounting for cortisol levels or other stress hormones, measures of pair/pack persistence) ● There is an inappropriate understanding and consideration of tribal worldviews about wolves. Tribal worldviews of wolves are misconstrued as 'cultural benefits' tribes receive from the existence of a wolf population, when in fact tribal worldviews consider each individual wolf as a person and relative. Cultural respect and sensitivity towards such views, shared by many non-tribal members, demand the strict mitigation of lethal measures, especially recreational killing, as opposed to their current promotion in the plan. ● In general, all omissions of scientific literature, the arbitrary prioritization of policy objectives, the rhetoric of the plan and the dismissal

Name	Resident	Date	Time	Subject	Email Body
					of public values and concerns for wolves point towards a biased, unscientific and instrumental view of wolves that promotes values contrary to broad public perspectives on wolves. ● 'SOM' wolf estimation methodology " From a recent critique: The new methods sacrifice precision, but are believed to retain adequate accuracy and sensitivity to changing conditions for reliable decision-making. We review evidence for the accuracy, precision, and sensitivity of the new 'scaled occupancy model' (SOM) applied in Wisconsin. We conclude that the Wisconsin method would systematically overestimate wolf abundance by large (but currently incalculable) margins. Because Wisconsin, similar to other states, not only changed to unverified methods but also implemented widespread wolf killing, shortcomings in their estimates of wolf abundance may have far-reaching consequences for population viability and confidence in state wildlife managers. We discuss findings from Wisconsin alongside similar findings for other states' occupancy models being insensitive to human causes of mortality that have recently increased. Overall, Wisconsin's proposed method for estimating wolf abundance shows significant departures from best practices in scientific measurement. Verification will require independent replication and unbiased tests at multiple scales in multiple habitats under different human-induced mortality rates, and peer review before the new methods are considered reliable. Sandra Couch
Shawn Sullivan	Unknown	Jan222023	21:48:26	Rebuttal to your wolf management plan	The following comments are offered in rebuttal to your wolf management plan, which I have read and strongly disagree with: The current draft does not reflect the best available science, and is missing a substantial amount of scientific literature on (see reference list below): wolf ethology, sentience, sapience, sociability, agency and wellbeing, effectiveness of non-lethal interventions, especially relative to lethal ones, and the impact of widespread killing on wolves' physiology, behavior, wellbeing, social dynamics, ecological relationships and evolution. The above scientific omissions, combined with the emphasis on and promotion of sustainable recreational killing and consumptive users as a main management strategy, results in a biased plan that runs contrary to scientific evidence despite much of this omitted scientific evidence being more recent, numerous and of stronger inference. The plan should strictly curtail any lethal management of wolves except in extremely rare circumstances of immediate defense of life. A substantial body of research documenting human-caused mortality in North American wolves, including Wisconsin wolves, has found that policies allowing liberalized killing of wolves result in a direct increase in the hazard and incidence of illegal killings. Hounding or hound training, which are akin to allowing legalized dogfighting, should be illegal or severely restricted as this practice is extremely cruel to wolves and hounds alike and is not supported by the majority of hunters or the broad public. The plan should prioritize wolf protections and concentrate solely on non-lethal management of wolves in response to livestock conflicts to ensure ethical coexistence. Despite Act 169, which mandates a wolf hunting season, the department can still restrict the implementation of lethal methods by setting minimal quotas, including a quota of '0' wolves, restricting timing and methods. Several studies have proven a proactive non-lethal approach leads to better conflict mitigation. ● Lethal management often fails to provide a long-term solution to wolf predation and has the least consistent success rates when compared to non-lethal practices. In addition, there is significant evidence showing that lethal wolf management may be less functionally effective at mitigating subsequent livestock losses than non-lethal deterrents. The plan should require the implementation of abatement measures as well as the use of non-lethal conflict minimization techniques by domestic animal owners for the latter to receive compensation for confirmed predation. The plan also runs contrary to public values towards wolves (and omits mention of such majority values from the plan), despite department surveys evidencing that the broad public cares about wolves as individuals (and not just for the viability of the population). Given the recent liberalization of killing wolves by the state, it would be incredibly informative to note majority support of the following reasons for opposing a regulated wolf hunting/trapping season (which are all omitted from the plan): opposition to specific methods of harvest like hounds (64%) or traps (70%), feelings that hunting wolves is unnecessary (62%) or culturally offensive to Native American tribes (57%). All such reasons convey majority disagreement with practices currently promoted and endorsed by the legislature and the WDNR, and such a conflict between managers and the public should not only be acknowledged, but foregrounded and carefully considered in policy (instead of dismissed). Such decisions to omit literature or downplay evidence (e.g., such as majority opposition to killing wolves and their reasons) are contrary to principles of scientific integrity (e.g., present all relevant scientific evidence to the public) as well as ethics (e.g., disguising ethical decisions, such as recreational wolf killing, as robustly supported by science). Conflicting agency objectives (e.g., optimizing public hunting and conflict mitigation) are not only not acknowledged, but even misunderstood as harmonious, against the body of scientific evidence. That culminates in the prioritization of consumptive values and policies; e.g., according to the body of scientific literature, use of lethal methods, and 2 especially public hunts, are contrary to most objectives relevant to: harm mitigation, the wellbeing of wolves, their ecological roles, and their non-exploitative enjoyment (i.e., Objectives A, B, D and F). There is a stark lack of consideration for individual wolves, wolf population health (including wellbeing), and measurable indicators for assessing any harms barring disease prevalence (e.g., accounting for cortisol levels or other stress hormones, measures of pair/pack persistence) There is an inappropriate understanding and consideration of tribal worldviews about wolves. In general, all omissions of scientific literature, the arbitrary prioritization of policy objectives, the rhetoric of the plan and the dismissal of public values and concerns for wolves point towards a biased, unscientific and instrumental view of wolves that promotes values contrary to broad public perspectives on wolves. Shawn Sullivan A concerned citizen STOP KILLING WOLVES BY TRAPS ANY OTHER MEANS, AND STOP HUNTING WOLVES
Christine Hein	Unknown	Jan232023	21:16:50	Wolf Management Plan comments	Hello to whom it may concern, I read the plan for wolves and had a few comments to share. 1. I don't agree with hunting or trapping of wolves for any circumstances. Wolves should be protected from any hunting or trapping. The wolf population needs to increase not decrease at the whim of state officials. 2. I don't think ranchers or farmers should be able to shoot a wolf if found on their property or kill a wolf it its takes their livestock. Wolves hunt so they can eat and live just like any other animal in the wild (coyote, bear, eagle, bobcat, etc). And when a wolf hunts they do not know the difference between an owned animal like livestock versus wildlife like deer or rabbits. If a rancher loses livestock to wolves, they should use deterrents such as fencing, guard dogs and motion lights. And if livestock is taken, the rancher should consider that the price of doing business in wolf country. Wolves are the endangered ones, not livestock that numbers in the thousands which are being raised for their meat anyway. The wolf management plan should have no lethal management of wolves except in extremely rare circumstances of immediate defense of human life. Sincerely, Christine Hein
Tykie Wescott	Y	Jan252023	9:09:38	Wolf Plan Management	January 25, 2023 Wolf Plan Comments. Why should there be a buffer zone around the reservations? Outside of the reservation bounderies is mostly private land and you are saying we can't legally hunt on our own property? I think the DNR is doing a terrible job. You are tone deaf to the wishes of northern Wisconsin. Look at the votes in counties up here concerning wolf populations. If wolves were in southern Wisconsin at the population there is in northern Wisconsin, the attitude towards wolves would change. You are not helping balance the number of deer vs. the number of wolves. It has had a huge impact on the economy up here during deer season. 1) Why are you going back on the plan you sold to Wisconsinites, that the wolf population goal was 350? 2) Why don't you listen to the people where the wolves are prevelant in the northern part of Wisconsin? Most of your wolf advocates live where there are no

Name	Resident	Date	Time	Subject	Email Body
					wolves, they have no idea of the problems wolves have caused. 3) Farmers are losing money due to wolves killing or harrassing their livestock in northern Wisconsin. 4) Our deer population has plummeted significantly in the last twenty years, the same time the wolf populaton has increased. 5) Northern Wisconsin was the destination for many deer hunters. Now the hunters are as scarce as the deer. 6) It's all about southern Wisconsin because you think that's where the political votes are. Don Wescott Springstead, WI (northern)
Erich Schmidtke	Unknown	Jan252023	16:34:03	Wolf Management Plan	I feel that wolf numbers should be WAY higher than what you've proposed in the past. We have so many deer and turkeys and Canada geese which tend to have no predators. More wolves could fill that need . As an orchard and wood lot owner I have to take extraordinary measures to protect both established and new trees from predation by deer. Basically whatever I don't protect gets browsed. Thank you, Erich Schmidtke
Karen Gunderson	Y	Jan252023	16:59:10	DNR Wolf Management	I encourage the DNR to pursue their new proposed wolf management plan, which relies on monitoring the wolf population in the 6 zones and determining only then whether to reduce the wolf population. I live in the city of Madison, so don't have interactions with wolves. However, I think they contribute significantly to a balanced ecosystem and are important in many ways, other than as targets for hunters. I would like to see humans co-exist with the wolves as much as possible. Thank you for your thoughtfulness in coming up with a new management plan and allowing public input on that plan. Karen Gunderson Madison WI
Marilyn Evenson	N	Jan252023	19:18:19	Draft 2022 Wolf Management Plan comments	Last November the WDNR released their Draft 2022 Wolf Management Plan. Altho the plan contains improvement, it is far from reflecting the best available science, ethics, & broad public values that should guide wolf policy & coexistence. Science should include: 1. Wolf ethology, sentience, & wellbeing 2. Effectiveness of non-lethal interventions. 3. The impact of widespread killing. Hounding or hound training should be illegal as it is extremely cruel to both wolves & dogs.The plan should curtail any lethal management of wolves except in rare occasions. I support increasing protections for wolves, requiring non-lethal conflict interventions, & banning recreational killing. The wolves are a very important part of the ecosystem & biodiversity. Man nearly eradicated them decades ago. That should never happen again. Most people do not approve of hunting wolves or anything else that disturbs Nature. Thank you for accepting my comments. Marilyn Evenson [redacted] Norwalk, OH 44857[redacted]
Linea Anthony	Y	Jan262023	0:31:41	A sane program to protect our environment's natural predators.	We must have sane, ecologically based programs that deal with the necessity of natural predators in our environment. We cannot allow the small group of selfish, self-serving greed driven hunters, with a wanton disregard for their existence rule the majority of the true, nature loving populace. Linea Anthony Racine
Deb Beduhn	Unknown	Jan262023	9:40:40	Wolf comment	I would like to comment and make my views known on the wolf management plan. I agree that the DNR should not establish a statewide population goal. I agree that it should monitor local populations within the hunting zones. I believe that the current population of 970 is too low and there should be no cap. Regarding the hunting of wolves, should the population become too large (and I don't know what number that would be), I propose that only native, indigenous members of our tribes be allowed to hunt the wolves. There is no reason for anyone else to hunt wolves in Wisconsin. From the last hunt it was very apparent that the hunters who participated and over-hunted the population were merely those with the killer instinct. Killing for sport. The tribe members who would do the hunting would treat the animal with respect and use the animal fully for food and other uses. It was only recently that the wolf was endangered in Wisconsin. We don't want to go back there again. Respectfully, Deborah Beduhn
jan Christensen	Unknown	Jan262023	9:43:48	Wolf Management Plan Comments	When walking into church I see, hanging from a wire, an ornament of a dove. In Wisconsin we kill mourning doves. When Wisconsin hunters harvested 80% over the allotted Wolf kill, it was big news on the Internet. The image of a Wisconsinite was that of a crazed, long haired man lashing out at his pack of dogs as they went on a killing spree. Is it any wonder that modern technology companies avoid our state? Adopt a senior pet. ;-)
Larry Zucollo	Unknown	Jan262023	10:33:32	my opinion	I would like the original goal of 350 wolves upheld and a yearly season to be held to maintain this goal.
Bob Paddock	Y	Jan262023	12:35:00	Voicemail	Hello, good afternoon. This is Bob Paddock in Augusta, WI. My telephone number is [redacted] I have a comment concerning the wolf management areas. I was really, really happy to see that the DNR made the deer management area for the southeast part of Eau Claire County. To coincide with what it was many years ago. That is to coincide with Hwy. 27 to 12 and keep on 2712 to the county line in the South. The new While our wolf plan does not have that same boundary, it goes down R to Hwy. 10 and then go to the cross that eliminates a little triangle in there. It's not very much, but definitely is more farm and agriculture than it is where the line is now drawn. It also makes sense to keep the prey species for wolf, IE whitetail deer. And Wolf the same So I would really encourage you guys to make that boundary the same and that being down 27212 and 27 together and then take 27, continue on 27 all the way to the southeast corner of Old Claire County, that being the boundary line for Management Unit 5. Thanks so much for your time. Bye bye.
Chryss Veirauch	Y	Jan262023	15:36:58	Wolf Forum	Greetings: The one recommendation I have after reading through the 2022 Wolf Management Plan, would be to take hunting with dogs out of the hunting/trapping method of wolf hunting. After the fiasco the Dept. of Natural Resource had with the latest hunt and all the horrible bad state and national press they got from hunters and non-hunters alike, one would think hunting wolves with dogs would not even come close to being considered. Animal rights advocates are already jumping on the bandwagon about the 2022 Wolf Management Plan because there are parts of the plan that include using dogs to hunt wolves. There will be an onslaught of reporters, anti-hunters, pro-wolf people are going to be parked all over the state of WI if dogs are allowed to be used. Let the trappers and rifle people do the hunting and save yourselves a lot of really bad press and headaches by pulling the use of dogs out of the mix. It only makes sense. Chryss Veirauch -- Christine Veirauch Beecher-Dunbar-Pembine K-12 School Counselor [redacted] Pembine, WI 54156 [redacted]
Mia Armstrong	Unknown	Jan262023	22:54:26	Public Comment--Please Protect Wolves	Dear Wisconsin Department Of Natural Resources, Please include protections for wolves in Wisconsin by ensuring that wolves receive full consideration as a species that should be allowed to exist as they have for thousands of years. Please sign into law that you will use non-lethal means to enable the wolves to co-exist with other residents of Wisconsin. Wolves are an imperative part of the entire ecosystem, and if the wolf population suffers, so does everything else in the state, from other animals, to trees and plants, even to the rivers and the landscape. As an apex species, wolves provide far more benefits to our environment when we allow them to live than when we kill them. They form close family ties, as do humans, and we need to make sure we do not continually traumatize them when we hunt them and kill their family members and friends. In addition, wolves need to have enough diversity in their gene pool to continue their species, so again, it is important that we do not continue to kill them as a means of management. Please also ban recreational killing of these awesome animals!

Name	Resident	Date	Time	Subject	Email Body
					Long before humans inhabited the area we call Wisconsin,□ wolves thrived here and helped create the beauty and bounty of America. Wolves deserve our protection. Please do not allow their slaughter. Thank you for listening to my comments! Mia Laurence
claudio serranegra	Unknown	Jan272023	9:04:11	Protect wolves in Wisconsin	I am in favor of increasing protections for wolves, requiring non-lethal interventions in conflicts and banning recreational killing.
Felicia Kelley	Unknown	Jan272023	20:04:19	WOLVES	STOP KILLING WOLVES THEY'RE GOOD FOR OUR ENVIRONMENT ¼ï¸□ GOD PUT THEM HERE FOR A REASON ¼ï¸□ SAVE THE WOLVES¼ï¸□¼ï¸□¼ï¸□ Felicia M. Kelley
Scott Block	Unknown	Jan302023	10:19:08	wolf managment	To Whom it may Concern, When coming up with a wolf management plan, I believe that science and facts should be the driving factors behind the decision and NOT personal opinions and/or the personal opinion from organizations and lobbyists. Hunters and farmers have strong uneducated or informed opinions and taking the word or comment from any group or organization affiliated with these said categorize is not the way to make laws and decide the fate of any wildlife. Thank you
David M Boden	Y	Feb12023	10:42:42	FW: DNR Website Information Request: Wildlife Information	To those directly involved with the Wisconsin DNR wolf management program/proposal. I grew up in the Western Upper Peninsula of Michigan and graduated from Northern Michigan University in Marquette, Michigan. I currently live in Appleton, Wisconsin and graduated with masters from the University of Wisconsin, Madison. I am writing to express my views on the most recent Wisconsin DNR gray wolf management plan, released 11/9/22. First off, for the DNR not to offer community listening sessions regarding the plan is to not be transparent and to not serve public interest. Thanks goes out the the Wisconsin Wildlife Federation (WWF) for taking the lead in sponsoring public listening sessions regarding the newly released DNR wolf plan. While at Northern Michigan in the mid 1970's, I was interested and supported Professor Dr. Robinson's efforts to reintroduce gray wolves to the Western Upper Peninsula of Michigan. These efforts did not involved the management of wolf numbers as the future population was never perceived to becoming too large, creating public issues. Clearly, this is now the case as wolf numbers are far, far greater than the original 350 population goal in Wisconsin. This considered, I agree with the WWF and the Wisconsin Bowhunters Association (WBA) regarding their recent communications to you regarding the proposed Wisconsin Wolf Plan. Specifically, and most importantly I support the 350 wolf population goal in Wisconsin. I urge you to set and maintain this goal moving forward. To abandon a population goal within the wolf plan is to abandon a clear actionable management objective. The Wisconsin and Upper Michigan gray wolf population deserves to be managed in their best interest and in the best interest of all stake holders who live and work in wolf habitat regions of Wisconsin. Clearly, our Wisconsin DNR has effectively managed our Black Bear populations. It's time to use this management model to manage our Gray Wolf population. Thanks for listening. With respect, David M. Boden Contact Information: Name: David M Boden Boden Phone: [redacted]
marcy	Unknown	Feb22023	11:12:34	wolf managment	people move out to the country they know tnat there is wildlife out there they should be prepared for that alson why are you giving wolf damage payments to people that use dogs for hunting they know that the wildlife is going to fight back for their lives or protect their young dont always blame the wolf they kill to eat or feed their family if they have 10 acres of land to be on and you build housus on it that brings it down so dont always blame wildlife alot of people just dont like wolves and want to seen them gone
Bryon Sundberg	N	Feb22023	11:48:50	Wolf Protections	I support protections for wolves. And I oppose any plan that includes recreational killing and other lethal options. Scientific facts show that lethal options are not necessary. I strongly urge you to follow the science and adopt a plan that only includes non-killing and non-lethal options. Thank you. Bryon Sundberg Durham, NC
Sue McNally	Unknown	Feb22023	11:57:12	Wolves	I am in favor of increasing wolf protections, requiring non-lethal conflict interventions, and banning recreational killing. Thank you.
Tim Fox	Unknown	Feb22023	12:03:22	Wolf plan	Please limit wolf population to the original target, 300 and some. This will reduce; deer, elk, dog and livestock predation. Most importantly reduce human and wolf conflicts and threats to local and recreating people. Also disagree with compensating hunters for dog losses. Thank you Tim Fox
Craig Carlson	Unknown	Feb22023	13:21:05	WISCONSIN WOLVES	WOLVES ARE PREDATORS THAT FIT INTO THE CYCLE OF LIFE IN OUR WILDERNESS, & FOREST ENVIRONMENTS! THEY ACTUALLY HELP TO KEEP NATURE'S BALANCE OF LIFE WORKING SO NO PESTS OR SMALL PREDATORS, GET OUT OF HAND THRU RISING POPULATIONS IN THE RURAL AREAS!!! CRAIG L CARLSON
Christina DeRespiris	Unknown	Feb22023	13:24:59	Wisconsin Wolf Management Program	We appreciate the efforts of all WDNR staff involved in updating the state's wolf management plan. Although we believe the current plan needs significant updating (see next section), we recognize the efforts and improvements made to the previous plan, including: ●□ Wolves in WI will no longer be managed by reference to the old numerical goal of 350 wolves. ●□ There is much greater recognition of the ecological role of wolves ●□ The inclusion of a social survey, which notes increased positive views of wolves, knowledge of their ecological roles and increased opposition to the motives and methods for killing wolves ●□ The adoption of proposed buffer zones around tribal reservations (i.e., previously no buffer zones existed) What we don't like: ●□ The current draft does not reflect the best available science, and is missing a substantial amount of scientific literature on (see reference list below): ● wolf ethology, sentience, sapience, sociability, agency and wellbeing ● effectiveness of non-lethal interventions, especially relative to lethal ones ● the impact of widespread killing on wolves' physiology, behavior, wellbeing, social dynamics, ecological relationships and evolution ●□ The above scientific omissions, combined with the emphasis on and promotion of sustainable recreational killing and consumptive users as a main management strategy, results in a biased plan that runs contrary to scientific evidence despite much of this omitted scientific evidence being more recent, numerous and of stronger inference. ●□ The plan should strictly curtail any lethal management of wolves except in extremely rare circumstances of immediate defense of life. ● A substantial body of research documenting human-caused mortality in North American wolves, including Wisconsin wolves, has found that policies allowing liberalized killing of wolves result in a direct increase in the hazard and incidence of illegal killings. ● Hounding or hound training, which are akin to allowing legalized dogfighting, should be illegal or severely restricted as this practice is extremely cruel to wolves and hounds alike and is not supported by the majority of hunters or the broad public. ●□ The plan should prioritize wolf protections and concentrate solely on non-lethal management of wolves in response to livestock conflicts to ensure ethical coexistence. ● Despite Act 169, which mandates a wolf hunting season, the department can still restrict the implementation of lethal methods by setting minimal quotas, including a quota of '0' wolves, restricting timing and methods. ● Several studies have proven a proactive non-lethal approach leads to better conflict mitigation. ● Lethal management often fails to provide a long-term solution to wolf predation and has the least consistent success rates when compared to non-lethal practices. In addition, there is significant evidence showing that lethal wolf management may be less functionally effective at mitigating subsequent livestock losses than non-lethal deterrents. ●□ The plan should require the implementation of abatement measures as well as the use of non-lethal conflict minimization techniques by domestic animal owners for the latter to receive compensation for confirmed predation. ●□ The plan also runs contrary to public values towards wolves (and omits mention of such majority values from the plan), despite department surveys evidencing that the broad public cares about wolves as individuals (and not just for the viability of the population). Given the recent liberalization of killing wolves by the state, it would be incredibly informative to note majority support of the following reasons for opposing a regulated wolf hunting/trapping season (which are all omitted from the plan): opposition to specific methods of harvest like hounds (64%) or traps (70%), feelings that hunting wolves is unnecessary (62%) or culturally

Name	Resident	Date	Time	Subject	Email Body
					offensive to Native American tribes (57%). ● All such reasons convey majority disagreement with practices currently promoted and endorsed by the legislature and the WDNR, and such a conflict between managers and the public should not only be acknowledged, but foregrounded and carefully considered in policy (instead of dismissed). ● Such decisions to omit literature or downplay evidence (e.g., such as majority opposition to killing wolves and their reasons) are contrary to principles of scientific integrity (e.g., present all relevant scientific evidence to the public) as well as ethics (e.g., disguising ethical decisions, such as recreational wolf killing, as robustly supported by science). ● Conflicting agency objectives (e.g., optimizing public hunting and conflict mitigation) are not only not acknowledged, but even misunderstood as harmonious, against the body of scientific evidence. That culminates in the prioritization of consumptive values and policies; e.g., according to the body of scientific literature, use of lethal methods, and 2 especially public hunts, are contrary to most objectives relevant to: harm mitigation, the wellbeing of wolves, their ecological roles, and their non-exploitative enjoyment (i.e., Objectives A, B, D and F). ● There is a stark lack of consideration for individual wolves, wolf population health (including wellbeing), and measurable indicators for assessing any harms barring disease prevalence (e.g., accounting for cortisol levels or other stress hormones, measures of pair/pack persistence) ● There is an inappropriate understanding and consideration of tribal worldviews about wolves. Tribal worldviews of wolves are misconstrued as 'cultural benefits' tribes receive from the existence of a wolf population, when in fact tribal worldviews consider each individual wolf as a person and relative. Cultural respect and sensitivity towards such views, shared by many non-tribal members, demand the strict mitigation of lethal measures, especially recreational killing, as opposed to their current promotion in the plan. ● In general, all omissions of scientific literature, the arbitrary prioritization of policy objectives, the rhetoric of the plan and the dismissal of public values and concerns for wolves point towards a biased, unscientific and instrumental view of wolves that promotes values contrary to broad public perspectives on wolves. ● 'SOM' wolf estimation methodology " From a recent critique: The new methods sacrifice precision, but are believed to retain adequate accuracy and sensitivity to changing conditions for reliable decision-making. We review evidence for the accuracy, precision, and sensitivity of the new 'scaled occupancy model' (SOM) applied in Wisconsin. We conclude that the Wisconsin method would systematically overestimate wolf abundance by large (but currently incalculable) margins. Because Wisconsin, similar to other states, not only changed to unverified methods but also implemented widespread wolf killing, shortcomings in their estimates of wolf abundance may have far-reaching consequences for population viability and confidence in state wildlife managers. We discuss findings from Wisconsin alongside similar findings for other states' occupancy models being insensitive to human causes of mortality that have recently increased. Overall, Wisconsin's proposed method for estimating wolf abundance shows significant departures from best practices in scientific measurement. Verification will require independent replication and unbiased tests at multiple scales in multiple habitats under different human-induced mortality rates, and peer review before the new methods are considered reliable. (Treves & Santiago-Ãvila, 2023) Thank you. Christina DeRespiris [redacted]
Donna Selquist	Y	Feb22023	14:13:10	Wolves in WI	Wolves are aq natural and necessary part of a healthy WI environment. They keep prey animal numbers in check, and rarely target healthy strong individuals. Any incidental loss of livestock or family pets due to unusual circumstances can be, and is, compensable upon proof from public funds. Given the chance to regulate their own numbers and choose their own territories, wolves will do so. Just leave them alone to live their lives in the way that Nature intended. It should be permissible to kill a wolf only when its behavior threatens a human or other protected animal's life, and even then only after other non-lethal measures have been tried. Thank you. Donna Selquist Florence 54121
	Unknown	Feb22023	14:14:06	PLEASE ACT IN COMPASSION TOWARD THE PROTECTION OF WOLVES IN THE ECOSYSTEM..!!	Wolves are some of the most sensitive, intelligent family oriented beings on the planet! They need our protection.. not to be hunted and killed. They positively effect the ecosystems of which they are a part. They are a NECESSARY part of a healthy ecosystem. Please find compassion in your hearts and make a decision that serves all life, by protecting wolves! Thank you for your kind understanding. Blessings of Love.
Linore Blackstone	Unknown	Feb22023	14:33:02	Wolf "management" plan	Dear DNR, my comments about the management address the agencies' practice of target management with administrative rules not made public, manipulated science, outdated science, failure to respect the integrity of the wolves, lack of respect, disregard, or outright hostility. Millions of people have lost respect for and trust in the federal and state wildlife agencies because protecting wildlife is not the priority for these agencies. Consider the consequences. Consider that humans have assumed the attitude that we can be and are everywhere because we believe that everywhere is ours; thus, the ongoing collapse of wild lands and wildlife. Linore Blackstone
Alison James	N	Feb22023	14:59:25	Comment on the wolf "Management Plan"	My comment: At the start of the document you list the supporters of this plan. Every entity listed has something to gain by backing this plan. Either by hunting or a lazy way of stopping predation. In fact, some of those listed are infamous in their desire to hunt and kill. Your plan is not really a "management plan" but rather a devastation plan. Do not be proud of the document, there is nothing there but death. Disappointing. Alison James Sandy Hook, CT
jean publiee	Unknown	Feb22023	15:03:08	Fwd: Speak out for wolves in Wisconsin!	i want wolves protected from the insane people with guns who want to murdedr and kill as their job in life. i find that anmals are part of our ecology and their lives help oiur lives. we respect and want protection for wolves, bears and all animals.none are "game". none are "game". this comment is for the public record. please receipt., jean publiee [redacted]
Rena Franchi	N	Feb22023	15:03:41	Wolf Management Plan	Wisconsin Department of Natural Resources, I loudly and strongly speak in favor of wolf protections. We appreciate the efforts of all WDNR staff involved in updating the state's wolf management plan. Greg Goodmacher	Unknown	Feb22023	19:04:09	Protecting Wolves	Dear Wisconsin Government Official, Please save the Wisconsin wolves. They keep the environment in balance, and they are iconic American creatures. Hunting and killing them is wrong. A few years ago, I visited Wisconsin, and while on an eco-tour, I spotted one wolf. It was an unforgettable experience that I told many people about. You should promote nature and ecotourism involving wolves. Sincerely, Greg
Claudia Reed	Unknown	Feb22023	20:09:31	Proposed wolf management plan	Wolves should be protected. They have a positive impact on the health of our ecosystems. In your newest Wolf Management Plan, please be sure to ban recreational killing, and to require non-lethal conflict interventions. Thank you, Claudia Reed
Jeff	Unknown	Feb22023	22:45:08	Help needed	Save wolves instead of slaughtering them. Jeff God is Great.
Steve Nimz	Unknown	Feb32023	5:21:52	Wolf Plan	I have 200 acres of hunting land in Harshaw WI (54529). My brother in law has an adjoining 200 acres. I regularly see one or more wolves on my trail camera (not coyotes- one of the wolves has a collar but that one has not been seen for a while). Deer have been run off or killed by these wolves and hunting success has decreased dramatically. I am in favor of a wolf management plan which limits the proliferation of these animals (the 350 annual wolf harvest. Sincerly , Steve Nimz
Curtis and Jane Hoffman	N	Feb32023	9:50:21	Please do not let humans kill off the wolves	* We are in favor of increasing wolf protections, requiring non-lethal conflict interventions, and banning recreational killing. * * We have seen the beauty and wonder of wolves in Yellowstone Park and read about the ways that they are helping the ecosystem. Wolves are not the only animals that prey on livestock, and the government is repaying ranchers for any losses. When I was younger, they killed off all of the wolves in Texas. What a horrible thing that was, and now we just have more coyotes and bobcats that are killing household pets in our cities and can pose a threat to small children. The good lord created the wolf to balance nature. Please do not let man just kill them off. They add so much to our world. Thank you. Curtis and Jane Hoffman Dallas TX
Diane Darcy	Unknown	Feb32023	11:22:01	Wolf protection	I'm urging you to support legislation which will support wolf protections. Cordially, Diane D'arcy
Tim White	N	Feb32023	12:57:04	Protect the wolves in Wisconsin	The current draft on wolf management, does not reflect the best available science, and is missing a substantial amount of scientific literature on (see reference list below): wolf ethology, sentience, sapience, sociability, agency and wellbeing; effectiveness of non-lethal interventions, especially relative to lethal ones; and the impact of widespread killing on wolves' physiology, behavior, wellbeing, social dynamics, ecological relationships and evolution. The above scientific omissions, combined with the emphasis on and promotion of sustainable recreational killing and consumptive users as a main management strategy, results in a biased plan that runs contrary to scientific evidence despite much of this omitted scientific evidence being more recent, numerous and of stronger inference. In light of this, I urge you not to adopt this plan. Christine White [redacted] Tucson, AZ 85739
Jane August	Unknown	Feb32023	13:02:46	Wolves	Do not kill the wolves
Shabaka Jones	Unknown	Feb32023	13:56:42	Protect the wolves	Please place laws and regulations in place that protect wolves and allow them to thrive. Wildlife benefits the earth and were created with a GREAT purpose!
Susan Welsford	N	Feb42023	13:40:33	Wolves	Please take any actions necessary to protect wolves and to stop legislation for wolf hunts in Wisconsin. I am desperately seeking protection for this severely threatened species and its return to the Endangered Species List. Loss of these two things will push the species to extinction. Wisconsin FWS and DNR is well aware of the importance of this predator in nature's biological ecosystem from the Isle Royale events in Michigan. The wolf recovery system is deeply flawed, i.e. erroneous and poorly calculated population estimates, influence and dishonesty of farmers, greed of the hunting/trapping and firearms industries, climate change events not planned for, disease of the species or a species they are dependent on, urban sprawl, and the abject failure of the state DNR/FWS and political systems. In 1989, there were only three gray wolves left in Michigan's U.P. Hunting and trapping nearly drove the species to extinction before, and wolves are on the brink of extinction again. We must allow them the required protections and acreage to live to expand their genetic pool. Without a valid and robust wolf protection plan, this vital species will be destined for extinction. Susan Welsford Norton Shores, MI 8th
Nancy Garret	N	Feb42023	15:12:01	Protecting wolves in Wisconsin	Hello, I live in California where wolves are treated as an integral part of nature that deserves consideration and respect. I support increasing protections for wolves, requiring non-lethal conflict interventions and banning recreational killing. A draft wolf management plan should prioritize wolf protections and concentrate solely on non-lethal management of wolves in response to livestock conflicts. I'm counting on you to do the right thing for these animals to ensure ethical coexistence in Wisconsin. Thank you. Nancy Garret
Adriana Nunez	Unknown	Feb42023	15:29:56	Please save Wolves!	We appreciate the efforts of all WDNR staff involved in updating the state's wolf management plan. Although we believe the current plan needs significant updating (see next section), we recognize the efforts and improvements made to the previous plan, including: ●⍰ Wolves in WI will no longer be managed by reference to the old numerical goal of 350 wolves. ●⍰ There is much greater recognition of the ecological role of wolves ●⍰ The inclusion of a social survey, which notes increased positive views of wolves, knowledge of their ecological roles and increased opposition to the motives and methods for killing wolves ●⍰ The adoption of proposed buffer zones around tribal reservations (i.e., previously no buffer zones existed) Thank you
Debbie Wall	N	Feb42023	18:09:54	Re: Wolf "management" plan	Our poor, poor planet is much too close to her tipping point for us to be enacting policies that will only serve to push her over the edge. We must preserve whatever precious little pristine wilderness remaining and re-wild much of that stolen from the animal nations. Since we've put a man on the moon, the human population has more than doubled while that of the wild animal nations has more than halved. The survivors, including wolves, need protection and deserve to live and raise their families in peace. We need to adopt peaceful co-existence and compassionate conservation strategies. Debbie Wall & The Gang of Fur Winnipeg, Manitoba Canada
virgene link	Unknown	Feb52023	0:41:14	Wolf Management Plan	To Whom It Concerns: The current draft does not reflect the best available science, and is missing a substantial amount of scientific literature on wolf ethology, sentience, sapience, sociability, agency and well being. The plan should strictly curtail any lethal management of wolves except in extremely rare circumstances of immediate defense of life. Effectiveness of non-lethal interventions and impact on well-being, physiology, behavior and social dynamics must be recognized. Use of baiting, hounds and killing in the den are unsporting. Please increase protections for wolves, requiring non-lethal conflict interventions and banning recreational killing. Earth is their only home too and they have an important role to play in the ecosystem. Thank you, Virgene Link-New
Jane Grove	Unknown	Feb52023	21:24:09	Wolf Management Plan	Hello, I am asking you to please do not allow hunting oh your precious wolves. You are lucky to have them in your state. There was no need for your callous open season⍰ on them recently. Your plan should allow compensation to any ranchers who lose sheep or cattle. Please protect your wolves. Don't kill them! Respectfully, Jane

Bryhn, Rhonda J	Unknown	Feb62023	8:34:50	input	Hello DNR, Please take this opinion into account when you consider how to manage WI's wolves: Wolves are a keystone species. They are intelligent, social and beautiful. Hunting and trapping of them should not be allowed. Instead, allow them to flourish, and provide education to the public that dispels the myths that cause them to be misunderstood. They deserve (like all creatures) to exist without exploitation and cruelty. Thank you, Rhonda
Carl Kringle	Y	Feb62023	9:01:36	Wolf management	Dear Sirs I have bought a hunting license for 71 years and voted in the spring hearings many of those years. I feel that it is a slap in the face when you don't follow the overwhelming majority of people that want a quota of 350 on wolf management. We are the people that are paying your wages, I think you should follow our wishes, not the wishes of the minority! Sincerely Carl Kringle Rice Lake WI
Samuel Kasprzak	Y	Feb62023	10:12:47	2023 Wolf Management Plan	This is a letter concerning the Wisconsin 2023 Wolf Management Plan. I have read the draft plan and done additional research concerning the history of Wisconsin's storied history with wolf and wildlife management. What I've found is very concerning. Now, before I go any further, I have to state that while I am a citizen of Wisconsin, I am not a scientist or a biologist and I am not a recognized authority on the subject of conservation. However, what I have to say is based firmly on sound science, recognized experts and a grounded sense of morals. What I'm going to say will be controversial, and I ask that whoever reads this follows through to the end. What I've written is constructive criticism, and at the end of this letter I propose real solutions and sensible advice. All I ask is that whoever this concerns will read this with an open mind. Wisconsin has had a storied history with wolves, much of it antagonistic. However, it is not unique, as every state in the U.S. has stories of wolves, or more specifically, the war we wage against them. I bring this up to make this point; it is impossible to make intelligent decisions if we don't learn from the mistakes of this past. And to learn, we must own up to our mistakes and do better. This is a chance to redeem ourselves. To set the record straight, wolves aren't even close to being a recovered species. This declaration is fraudulent, ignorant and completely ungrounded from reality. Further, any legislation based on this "recovered" declaration are themselves fraudulent and ignorant of the reality of the situation. Wolves are at a crossroad at this time, and with proper action, wolves could return and restore the ecosystem of their former range, or they could wither and die, bringing the North American ecosystem with them. So, let's get right to the heart of the issue. Wolf Management. This is a joke. You can't possibly "manage" something you can't fully understand. And this isn't just about wolves, but for wildlife in general. The natural world is made of hundreds of billions upon billions of living organisms interacting with each other at microscopic and macroscopic levels. And all these organisms from bacteria to badgers have personalities, characteristics that are completely unique to the individual. The complexity is staggering, making logical "management" impossible. To think anyone could decipher the vastness of the ecosystem into clear and precise calculations and formulas is destructively prideful and laughable. So, what then? Is sensible management possible, and if so, what does it look like? First, I'll show you what it doesn't look like. Wolf Harvesting and quotas are the first clear examples of destructive and inhumane management. The basic concept of wolf "quotas" is that somebody calculates this magic number of "sustainable" wolves in each area, then approves the killing of wolves that exceed the magic number. This is an atrocity at its best. The whole notion of animal "quotas" has to be eliminated if sensible action is seriously being considered. Another example of irresponsible management looks like the infamous "coyote killing contests" held in Wisconsin in the past. The very fact that coyotes can be hunted anytime of the year in virtually any quantity is despicable. So, what does proper "management" of Wisconsin's wildlife look like? It means wolf and other predator "quotas" should be eliminated altogether. A practice of "cause-and-effect" must be adopted, meaning that the Department of Natural Resources will handle individual animals that may be nuisances or pose a direct threat to human health. Next is the very notion of "management" itself. To best conserve the ecosystem, we must stop trying to control it. Wolves, as well as nature itself, don't need human intervention, quite the opposite in fact. Nature provides for itself, it balances population carrying capacities, diet, location, etc. For instance, deer in Waupaca County have been discovered with Chronic Wasting Disease, a well-known symptom of deer overpopulation due to a lack of natural predators. Additionally, deer collisions have become the third leading cause of vehicle impacts in Wisconsin, again from overpopulation. Concluding this letter, the question becomes, is it too much to ask in this supposed age of scientific enlightenment to simply leave wolves and other predators alone? Is a simple truth too much to accept in this often over-complicated world we've created? It's time to take a step back. It's time to take our hands off the controls, stop trying to play God, and let nature do what it's designed to do: bring balance. Sincerely, Samuel Kasprzak
Dale Verhage	Unknown	Feb62023	14:32:13	Wolf plan	I believe the wolf plan needs a quota number and I think it should stay at 350. Dale Verhage
Janell Copello	Unknown	Feb62023	20:11:17	real wolf protections in the proposed Wolf Management Plan	Attn: Department of Natural Resources, We can all expect to see wild animals, including coyotes, in our open spaces, parks and cities. It is now common and normal to see them during either the day or night. Coyotes are vocal when greeting family members and when reinforcing territory. Like most other wildlife, they don't vocalize when hunting so as not to attract competition. Coyotes are omnivorous, eating mostly rodents and rabbits, but also fruit, insects, vegetation, and carrion. Urban studies in both Chicago and Los Angeles show that less than 1% of a coyotes' diet is domestic cat. However, a coyote doesn't know the difference between a cat and a rabbit, so it's best to supervise pets at all times. To be 100% sure that no harm comes to our small domestic animals”from all manner of dangers, including cars, poisons, entrapment and coyotes/dogs/bobcats/owls”we need to supervise them carefully. That said, coyotes near human development are most likely encountered between dusk and early morning. Juvenile coyotes disperse in the fall (seeking mates and territory), so spotting them at any time of the day is not unusual. However, just because we don't see them often doesn't mean that they aren't around. What a coyote does best is stay out of our way. Here is the bad news: One coyote is killed every minute of every day in the U.S. What's their crime? Being seen. I think that most of us in any nature-appreciating part of the country would agree that to kill a beautiful animal because they dare to be seen is the real crime. Check out why relocating coyotes is not a viable solution (and, in fact, is illegal in many states): http://www.discoverwildcare.org/wildlife-resources/trapping-and-relocating-wildlife/<http://secure-web.cisco.com/125o-j3l01J3go0fKJbrTOhwcjU_NcrtbSt7iyICufMwtrKgMnoE6OpiZzD9PREIJQZzd7M6FjAXTjTLutMNLCRuWaotD0dGHQ_69_LMyrfVxrpNNZbu-oNp3aVomS-vwVODrABxrQtvY4RMRiHoPwog--pEagQe0zRVzxYZIwZ45Fed99FpsYYbQ92pK2EsaCUtPNVwMKnrkCGRYWqIbWQ46jVFRN-gK-Vz75ScsEbdBYN1SYl3ffD7MUG60-DwRAFc_P472BAJrUtbfgRR4oMLwkeTk6MBqV9y_EJHXsT7wT03tF4Ch0Uqlr7BZ-D24jU8SIIYGtTdv0Ax7p0Rm9A/http%3A%2F%2Fwww.discoverwildcare.org%2Fwildlife-resources%2Ftrapping-and-relocating-wildlife%2F>). The reality is that we have wild neighbors and we need to learn how to coexist and reduce negative encounters. And there is good news: You can inform yourself about coyote biology and behavior, seasonal expectations, coyote hazing and deterrents, from Project Coyote. Find the information online at www.projectcoyote.org<http://secure-web.cisco.com/1TvY8P_e1Dptfk6sRxpCBsnBrNGctPsHA3Gl7a7yOllknDPz-bm42MyHzXjhXkrVf0YuLRYu5ak1uzht43bb_VPwumZPEVcrcmAbBmxPKuXjcHLWa_qdqmj2yyuXZvoq9Agqy0kU9ud9EZg-Olbkp0AfzeEg7C8S_YR3lTrPc8Xk2PrYxyw8yH7aQRAWRs3oP0hGM5P4433asAsWUmHqvyEIsk1srPgNKvhxXRo5I4Rz0T8BzabPyaIJJ_BQmZlvVwAZEDZykd5ucpWxoWuUgPvMb5_lrhxSnykkNOFs8Z8vQXjn540Rh2sAJs5MKHddGFS9-XdvsGiEmSTHFtfq4lg/http%3A%2F%2Fwww.projectcoyote.org>, and check out the Resources page: http://www.projectcoyote.org/resources/. Karen Eckert	Unknown	Feb72023	15:11:08	End Hounding with Hounds against wolves	Throwing the dogs to the wolves. A metaphor but unfortunately a fact in Wisconsin Did you know that dog fighting is legal in the state of Wisconsin? Did you know that dogs injured or killed while fighting wolves are paid by the Wisconsin DNR up to $2500? Not only is using dogs to fight wild animals legal in Wisconsin, it is also encouraged by state authorities. But under Wisconsin Legislation 951.08 Instigating fights between animals. (1) No person may intentionally instigate, promote, aid or abet as a principal, agent or employee, or participate in the earnings from, or intentionally maintain or allow any place to be used for or other fight between the same or different kinds of animals (2) No person may own, possess, keep or train any animal with the intent that the animal be engaged in an exhibition of fighting. SO WHY THEN IS HOUNDING WOLVES STILL LEGAL ? In the north woods of Wisconsin there is a disturbing underbelly of Wisconsin's hunting community that is legally allowed to use packs against wild animals. In fact, with the absence of a permit and almost no regulations, Wisconsin has become the preeminent location for those that hound. Each year starting July 1 until mid-October, Wisconsin allows hounders from all over the country to descend upon our public lands, including our national forests, to pit their packs of hounds against wildlife . If the legal animal fighting that occurs during this training period isn't enough, each year dozens of hounds are allegedly killed by gray wolves that are defending their family rendezvous areas from the invading hounds. Human families defend their family if danger is near, so why wouldn't a wolf defend their family? To purposely invade a wolves family dynamic and expect them not to react is simply ignorant. Who are you to decide? When a hound turns up dead, even under the most dubious of circumstances, the Wisconsin DNR is required under law to immediately pay the hounder $2500. If the dog is deemed to have been injured by a wolf and survived, the DNR also pays for any related veterinarian care. Wisconsin is the only state in the country to pay people for losses when deliberately placing their animals in harm's way. Taxpayers need to be informed of this cruel and barbaric act of receiving 2500.00 and veterinary care if their hound is injured, even though this was done intentionally. Almost 3 million dollars of taxpayer money has been given to so-called hunters for this act since 1985. Dogs do not ask for this. Change the legislation and change the barbaric law of hounding with wolves in Wisconsin. -- Karen Eckert
K D	Unknown	Feb72023	16:29:34	Wolves are resistant to CWD	This makes wolves the perfect tool in protecting deer herds from the disease. And in minimizing cattle infection. Has the DNR been funded to advance this research. Do farmers get incentives to leave wolves alone or do they only get incentives for live stock incidents. Are hunters still getting money for deceased dogs killed by predators, or is there a possibility hunters could get rewarded for reporting wolves ALIVE in certain locations of equal monetary value. And be rewarded for the tagging of a wolf instead. Are we rewarding correctly, or the incentives and rewards not really helping the pack.
Thomas Wayne King	Y	Feb72023	18:19:23	Wolf comments by farmers who raise Registered Icelandic Sheep for Wool.	Hello. Wolves are highly beneficial to our forests and wildlife. Wolves must be protected better than WI has done in past. We have raised Registered Icelandic Sheep in northern Douglas County for the past 14 years, and have had NO wolf issues”ever”due to excellent fences, visual deterrents, scent repellants, and our respect shown to them. Wolves have reciprocated by leaving us and our flock alone. We side with the wolves and ask that DNR protect them fully. Thank you. Thomas and Debra King Wearing our sheep. Debbi makes wonderful sweaters and hats from our flock. [image0.jpeg] Thomas Wayne King & Debra Raye King Sunny Cove Registered Icelandic Sheep (SCI) Solon Springs, WI USA
Steve Kothman	Unknown	Feb72023	18:40:37	Wolf problem / No Deer	Attention DNR, Attached you will see a series of photos showing at least 8 wolves (possibly 9) feeding on a fresh deer kill. These photos were taken approximately 3.5 miles straight west of Dairyland Wisconsin. I have hunted this area for the past 30+ years and have never had this poor of deer hunting. There is wolf photos and scat everywhere you go. This area has a serious wolf problem and the system is way out of balance¦VERY FEW deer in this area. I have kids and grandkids that haven't even wanted to hunt the last couple years. My long time hunting group (5 hunters) are not hunting this year. Something has to be done to get the deer hunting closer what it used to be in the past years. I also know of many other deer hunters in the area who have the same sentiment. I'd like to know your position on this matter and what are the future plans to correct this problem. Additionally, I am very passionate that the DNR use a matrix number of 350 cap on the wolf population state wide. Also, there should not be a six mile buffer zone around tribal nations¦I am strongly against the six mile buffer zone!! We have a terrible wolf problem in north western Wisconsin Thank you in advance of your reply, Steve Kothman
Michael Skaw	Unknown	Feb72023	18:53:03	Wolf meeting	There needs to be a regulated wolf season in Wisconsin. The population is going to rise unchecked and grow out of control. Why is Wisconsin paying government trappers to reduce wolves in problem areas vs letting citizens pay to kill them. The money generated from licenses could be used to better population studies. Michael skaw
luke skaw	Unknown	Feb72023	19:32:10		There needs to be a regulated wolf season in Wisconsin. The population is going to rise unchecked and grow out of control. Why is Wisconsin paying government trappers to reduce wolves in problem areas vs letting citizens pay to kill them. The money generated from licenses could be used to better population studies.
Steve	Y	Feb72023	19:35:54	Wolf Management Plan Testimony	I'm Steve Pearson from Danbury, WI. I've lived in wolf country on wooded acreage for the last 44 years and I've watched the wolf population grow as a result of the protections of the Endangered Species Act. I raised two children here and now have 2 grandchildren living nearby. It's a good day when I see evidence of wolves, which I often do when winter camping on the St. Croix River near my home and on occasion on our property. It should be noted that not one human life has been lost to a wild wolf in the lower 48 states in the last 50 years compared the to 44 people killed by dogs in the U.S. in a recent year alone. The new draft plan for the most part does what I had hoped it would. It is science-based and has allowed for considerable public input. It is the result of a collaborative process with the tribes. I appreciate the hard work of all involved. Things I like include: * Removal of the numeric population goal

Name	Resident	Date	Time	Subject	Email Body
					which was arbitrary and not based on the best-available science. * I like that the plan creates low quota zones around Tribal lands where the Tribes requested it. * It's good to see that the plan reflects the public opinion survey that was released along with the plan that showed that opinions toward wolves have grown significantly more favorable towards wolves * I like the strong commitment to science and continued research on wolves. Things I'd like to see changed: Hounds chasing wolves for months is inhumane to both species as well as other species they encounter. I'm against using dogs to hunt wolves.The plan currently would allow hounds to chase wolves for training purposes during the wolf hunting season, across the entire state, until the very last wolf zone is closed. This could go on for months and would interfere with the wolf breeding season in late winter and break up well-established packs. The plan acknowledges that there are responsible farming practices and other non-lethal options to reduce wolf and livestock conflicts but I recognize that sometimes lethal means must be employed. Farmers should be able to protect their farm animals using lethal means if necessary and should be compensated for their losses. Having said that, I hope we never see a repeat of the wolf slaughter of 2021.
ronald bulman	N	Feb82023	8:31:26	Wolf regulatory plan (Personal Opinion)	I listened on zoom yesterday hearing the various opinions on your agencies wolf regulatory plan. I live in rural upstate New York. Use to be a non serioius deer hunter years ago. I feel as if I have somewhat of a stake in the survival of these wolves because to me they are not a resource but a National Treasure. Somewhat like the Buffalo and Wild Horses that run our praries. I think the name Wolves in itself upsets people. Going back long ago still in my time, I remember the big bad woof, even in comic books. A lot of people have been indoctrinated probably since birth to believe the Wolf is the worst of the worst and to be afraid of. Even in my small town, our history tells us that our area abounded with wolves and the settlers went out on wolf hunts to hill them off. How do you change this opinion but only by education. This is now the 21st. century. Humans would wipe out civilization in itself if there weren't people trying to save it. I do not want Wolves to be hunted. I do not want the use of dogs to hunt them down. I do not want the use of lethal traps of any kind or sort. No to trophy hunting. This is despicable. I do believe in safe zones. I do believe in the ranchers being reimbursed. The wolves have to be regulated to a degree so they don't create havoc on the ranchers. People have this mentality now that the world is theres for them to hike, camp and do whatever they want. No, this is absurb. They have to be educated that we will have to co-exist with the Wolf. They were here first. People have to take responsibility. It's there home not ours. Night hunting has to be stopped. I watch the TV show this Wild Kingdom. I see that if there is a animal problem, I don't see them selling hunting licences to kill, kill, kill. They trap the animal alive and remove it to an area where it no longer will be in contact with people. I think the opinions last night leaned towards non-lethal methods for the Wolf. Thank You Mr. Bulman, Penn Yan, New York
Sandy Swanek	Y	Feb82023	13:01:19	Wolf Management	DNR, Hello, I am and have been a resident of WI.,(Wausau), for most of my almost 64 years and truly appreciate all your efforts on this all important topic. I am not on zoom and couldn't join in on the public comments you offered on Feb. 7, 2023, however, I listened on YouTube to every comment and was moved by the amount of individuals that expressed their knowledge & compassion for these amazing family oriented wolf packs. Personally, I have studied Wolves for a few decades and almost took part in a refuge for them, sadly my situation at the time didn't allow me the time. Please stop the Hunting & hound chasing, it's wrong and as several of the commentators expressed, there has never been an attack on humans by the Wolves. Furthermore, as our population expands by building more subdivisions, we are obviously taking the natural habitats away from all the wildlife. In addition, I am in agreement with others that you have included the opinions of the Tribal community. Let us as a humane generation let the Wolves manage themselves. Hopefully, there's a way to financially help the agriculture community that's also detrimental to WI. to build the fences needed to protect their livestock. Additionally, the education on the Wolves needs a huge improvement to not only the public but n the school system as well. Thank you so very much for allowing the public (myself) to express our concerns that you will base further decisions on this subject. Respectfully, Sandra Swanek
David Skaw	Unknown	Feb82023	21:20:44	Wolf	Let us have a season to hunt problem wolves
Jennifer Argelander	Y	Feb92023	9:29:08	Comments on Wolf Plan	Hi, I want to thank you for a well written and very balanced plan. But here are my concerns. 1. We shouldn't be locked into a number for the base of the wolf population but a range would be nice so we the public know the minimum that the population would be, for example 700-1000 wolves in this state. 2. Good idea to look at it specific area for setting harvesting numbers. 3. Good idea that was presented about having wolves cull the CWD infected deer so keep the number of wolves high or protected until that can be accomplished. 4. Please limit the length of the hunting period--definitely stop before February. No more slaughters. 5. Decrease reporting time to 12 hours to report a kill rather than 24 hours because people wait to report. Must report via cell phones. 6. Need to address the use of dogs. And how they are used. Folks hunting together with 6 dogs each is an unfair advantage. Decrease the number of dogs used or not at all. Any hunt should be between the hunter and the hunted. It was disgraceful to see that over 80% of the kills used dogs in the last hunt. That is just slaughter and not the skill of hunting and those folks should be ashamed for being so lazy and unskilled. Thank you. Jennifer Argelander Madison WI
Connaughty, Tim	Y	Feb92023	10:21:50	Feedback - Wolf Advisory	Dear DNR, I may be past the window for feedback on this topic, but I saw on Madison TV that were you were seeking thoughts/opinions on this. Here is my two cents: Across the many aspects/priorities that our DNR manages and oversees, I do not know of one that is more politicized than the wolf. Because of the politics involved, the status of the wolf has been severely tainted. When the wolf population was deemed stable or recovered, it was then reversed due to politics. BECAUSE OF THIS, it is my opinion that a specific number of wolves must be decided on when thinking about recovery, state management, removal from endangered species, etc. With the current proposal to remove a specific number, it make this topic wide open to welcoming politics and bias into the conversation and decisions " instead of science. It feels to me like removing a specific population number has been put in place to precisely do just that " to allow the political bias to drive the decisions. Please, lets get back to science without politics involved " I know that is not an easy thing to do in this day and age. But we can start but instituting a specific population number for recovery and state management. Thank you, Tim Tim Connaughty Senior Director, Franchise Operations, Marriott International 1827 Harwood Court, Sun Prairie, Wis 53590 (312) 953-3869 (M) [cid:image001.png@01D93C6E.D4C268C0]<https://careers.marriott.com/>
Barbara Dukerschein	Y	Feb112023	10:37:15	Wolf Management Plan Comments...	I live in Chippewa County and I own woodland in Rusk County, where I often visit and hunt deer. As a member of the Wisconsin Conservation Congress, and our local CDAC, I am involved in listening to the public, landowners, and hunters regarding their views on the growing number of wolves. Many ask why we don't have a wolf plan and why doesn't it include a managed harvest? I support the position that the current Draft Wolf Management Plan must include a population goal of 350 wolves. By far the biggest concern is that there are too many wolves in parts of Wisconsin. Hunters want fewer wolves as they believe too many deer are killed by wolves. Farmers are concerned for their livestock when too many wolves are in their area. Some rural home owners are afraid their small animals and pets will be killed by wolves. They want to see the DNR return to an established number of wolves. The original number of 350 is the number they refer to most often. I also support the position that the current Draft of the Wolf Management Plan must be written to include more concern for control of wolf numbers where the highest population of wolves are found. The people of the parts of the state, where the wolves are found in high numbers, are paying the price of having too many wolves on the land. We need to manage wolves where too many wolves are found and not be influenced by the parts of the state where there are few or no wolves, but high public sentiment to

					manage the state's wolf population as a whole unit. Thank you for considering my concerns for the present Draft of the Wolf Management Plan. Don Dukerschein, [redacted] Chippewa Falls, WI 54729
Cassidy Thompson	Unknown	Feb12023	5:59:00	Protect Wolves Comments	To Whom It May Concern, We appreciate the efforts of all WDNR staff involved in updating the state's wolf management plan. Although we believe the current plan needs significant updating (see next section), we recognize the efforts and improvements made to the previous plan, including: Wolves in WI will no longer be managed by reference to the old numerical goal of 350 wolves. There is much greater recognition of the ecological role of wolves. The inclusion of a social survey, which notes increased positive views of wolves, knowledge of their ecological roles and increased opposition to the motives and methods for killing wolves. The adoption of proposed buffer zones around tribal reservations (i.e., previously no buffer zones existed.). However, there are some objections: The current draft does not reflect the best available science, and is missing a substantial amount of scientific literature on (see reference list below): Wolf ethology, sentience, sapience, sociability, agency and wellbeing. Effectiveness of non-lethal interventions, especially relative to lethal ones. The impact of widespread killing on wolves' physiology, behavior, wellbeing, social dynamics, ecological relationships and evolution. The above scientific omissions, combined with the emphasis on and promotion of sustainable recreational killing and consumptive users as a main management strategy, results in a biased plan that runs contrary to scientific evidence despite much of this omitted scientific evidence being more recent, numerous and of stronger inference. The plan should strictly curtail any lethal management of wolves except in extremely rare circumstances of immediate defense of life. A substantial body of research documenting human-caused mortality in North American wolves, including Wisconsin wolves, has found that policies allowing liberalized killing of wolves result in a direct increase in the hazard and incidence of illegal killings. Hounding or hound training, which are akin to allowing legalized dogfighting, should be illegal or severely restricted as this practice is extremely cruel to wolves and hounds alike and is not supported by the majority of hunters or the broad public. The plan should prioritize wolf protections and concentrate solely on non-lethal management of wolves in response to livestock conflicts to ensure ethical coexistence. Despite Act 169, which mandates a wolf hunting season, the department can still restrict the implementation of lethal methods by setting minimal quotas, including a quota of '0' wolves, restricting timing and methods. Several studies have proven a proactive non-lethal approach leads to better conflict mitigation. Lethal management often fails to provide a long-term solution to wolf predation and has the least consistent success rates when compared to non-lethal practices. In addition, there is significant evidence showing that lethal wolf management may be less functionally effective at mitigating subsequent livestock losses than non-lethal deterrents. The plan should require the implementation of abatement measures as well as the use of non-lethal conflict minimization techniques by domestic animal owners for the latter to receive compensation for confirmed predation. The plan also runs contrary to public values towards wolves (and omits mention of such majority values from the plan), despite department surveys evidencing that the broad public cares about wolves as individuals (and not just for the viability of the population). Given the recent liberalization of killing wolves by the state, it would be incredibly informative to note majority support of the following reasons for opposing a regulated wolf hunting/trapping season (which are all omitted from the plan): opposition to specific methods of harvest like hounds (64%) or traps (70%), feelings that hunting wolves is unnecessary (62%) or culturally offensive to Native American tribes (57%). All such reasons convey majority disagreement with practices currently promoted and endorsed by the legislature and the WDNR, and such a conflict between managers and the public should not only be acknowledged, but foregrounded and carefully considered in policy (instead of dismissed). Such decisions to omit literature or downplay evidence (e.g., such as majority opposition to killing wolves and their reasons) are contrary to principles of scientific integrity (e.g., present all relevant scientific evidence to the public) as well as ethics (e.g., disguising ethical decisions, such as recreational wolf killing, as robustly supported by science). Conflicting agency objectives (e.g., optimizing public hunting and conflict mitigation) are not only not acknowledged, but even misunderstood as harmonious, against the body of scientific evidence. That culminates in the prioritization of consumptive values and policies; e.g., according to the body of scientific literature, use of lethal methods, andespecially public hunts, are contrary to most objectives relevant to: harm mitigation, the wellbeing of wolves, their ecological roles, and their non-exploitative enjoyment (i.e., Objectives A, B, D and F). There is a stark lack of consideration for individual wolves, wolf population health (including wellbeing), and measurable indicators for assessing any harms barring disease prevalence (e.g., accounting for cortisol levels or other stress hormones, measures of pair/pack persistence) . There is an inappropriate understanding and consideration of tribal worldviews about wolves. Tribal worldviews of wolves are misconstrued as 'cultural benefits' tribes receive from the existence of a wolf population, when in fact tribal worldviews consider each individual wolf as a person and relative. Cultural respect and sensitivity towards such views, shared by many non-tribal members, demand the strict mitigation of lethal measures, especially recreational killing, as opposed to their current promotion in the plan. In general, all omissions of scientific literature, the arbitrary prioritization of policy objectives, the rhetoric of the plan and the dismissal of public values and concerns for wolves point towards a biased, unscientific and instrumental view of wolves thatpromotes values contrary to broad public perspectives on wolves. 'SOM' wolf estimation methodology – From a recent critique: "The new methods sacrifice precision, but are believed to retain adequate accuracy and sensitivity to changing conditions for reliable decision-making. We review evidence for the accuracy, precision, and sensitivity of the new 'scaled occupancy model' (SOM) applied in Wisconsin. We conclude that the Wisconsin method would systematically overestimate wolf abundance by large (but currently incalculable) margins. Because Wisconsin, similar to other states, not only changed to unverified methods but also implemented widespread wolf killing, shortcomings in their estimates of wolf abundance may have far-reaching consequences for population viability and confidence in state wildlife managers. We discuss findings from Wisconsin alongside similar findings for other states' occupancy models being insensitive to human causes of mortality that have recently increased. Overall, Wisconsin's proposed method for estimating wolf abundance shows significant departures from best practices in scientific measurement. Verification will require independent replication and unbiased tests at multiple scales in multiple habitats under different human-induced mortality rates, and peer review before the new methods are considered reliable." Russell Dukerschein	Y	Feb132023	18:53:28	wolf management	As a resident of Rusk County, I believe that we need to state a specific number of wolves needed in the state. There needs to be a bse number for the population to remain stable and survive. To leave it open ended is not, in my opinion, a good management practice. I also do not see any benefit to having a "buffer zone" around any Indian reservations. We don't have

Name	Resident	Date	Time	Subject	Email Body
					that buffer zone for bears, deer or any other game animal. The native americans already get their allotment of wolves to harvest. Whether or not they harvest their quota is up to them. No need to increase the safe space by having a buffer zone. I am not in favor of killing the last wolf. They have a place on the ecosystem, but you can't put a top tier predator into a space without having some controls. If the folks in the areas where there are no wolves are so intent on setting the rules, then put 250 in Dane county and 250 in Milwaukee county and see how they all like it. Russell Dukerschein [redacted] Glen Flora Wisconsin
Michele Statz	Y	Feb152023	19:04:48	Support for the Draft Wolf Management Plan	Dear Randy Johnson, Thank you and your team for the effort developing the 2022 draft Wisconsin Wolf Management Overall, I support the draft plan. I am pleased that it is guided by best available science, public input, and Tribal engagement- the core tenets of the best way to protect, conserve, and sustain natural resources! I also applaud the Department for conducting a very extensive and inclusive survey on the "public opinions regarding wolves in Wisconsin?. Things I support about the plan as written: ? The plan removes a numeric population goal, allowing for an adaptable population: I support the goal of a self-sustaining, self-regulating, and genetically diverse wolf population that maintains connectivity with wolf populations in neighboring states and fulfills their ecological roles. ? The plan creates low limit zones around Tribal lands where the Tribes requested it: These lands are treaty-protected with documented wolf packs. Making this update is an important and welcome addition to the plan. Ideally, the plan would expand these zones beyond just the few that are listed and further reduce the limit to one wolf per subzone. ? The plan is reflective of the public opinions survey that finds opinions toward wolves have grown significantly more favorable. ? There is expressed commitment to science and continued research with partners and acknowledgement that ?keystone species such as wolves are an important component of a healthy ecosystem?. ? The plan outlines the strategies related to increasing public education related to the implementation of non-lethal conflict deterrent techniques. ? I support the plan?s recommendations to pursue more administrative rules, including the reduction of the window to report wolf kills to 8 hours or less and making the purposeful destruction of occupied wolf dens illegal Things I would like to see added or reviewed before plan is finalized: ? The plan should outline the concerns with ACT 169 and recommend legislative changes so that the DNR is able to make decisions on wolf stewardship in alignment with the goals of the wolf plan. ? A recommendation that the department issues wolf hunting licenses which are valid only in the specific wolf management zone(s) specified on the license. ? The DNR should better regulate hound training on wolves. The DNR should close wolf-focused hound training activities as each wolf hunting zone closes. The plan currently would allow hounds to chase wolves for training purposes during the wolf hunting season, across the entire state, until the very last wolf zone is closed. This could go on for months and would interfere with the wolf breeding season and population tracking of which both occur in late winter. ? There is currently no guidance in plan for next review or update ? Ideally, the plan should include a provision to update every 5-7 years rather than simply being ?valid until it is replaced.? ? There should be permanent, ongoing oversight by a stakeholder group AND a science committee to oversee wolf stewardship in Wisconsin. The stakeholder group must be inclusive and recognize the importance of Tribal oversight. ? I recommend identifying specific metrics that will define successful wolf management in Wisconsin. Examples should include metrics include pack integrity, average pack size, distribution of CWD in wolf range, the relative distribution of wolves across the state, and genetic connectivity and flow between packs across the state. ? The plan acknowledges that there are responsible farming practices and other non-lethal options to reduce wolf and livestock conflicts but should recommend that the DNR prioritizes these opportunities. Bottom line: Please continue to push for more science-based research in our state as well as wolf co-existence education across Wisconsin. Thank you for your consideration and careful work involving the on-going wolf stewardship of wolves in our state. Sincerely, Michele Statz [redacted] Waunakee, WI 53597 [redacted] This message was sent by KnowWho, as a service provider, on behalf of an individual associated with Sierra Club. Daniel Zinsmeister	Y	Feb152023	19:23:13	Support for the Draft Wolf Management Plan	Dear Randy Johnson, Hi Randy, I have been involved in natural resource management for over 40 years, I own property in Marathon County and did my graduate work at UWSP. I want to emphasize the need to approach this issue based on the ecological importance of the gray wolf as a keystone species. I have experienced many forest habitats impacted by ungulate mismanagement. We are just beginning to realize the long-term effects to ecological systems,i.e. biodiversity of our northern hardwood forests. Unfortunately, we have only a few good studies identifying the impacts of unbalanced management of forests and need to approach future management with integrated practices. Please think about the diversity of future forests in your decisions. Thank you and your team for the effort developing the 2022 draft Wisconsin Wolf Management Overall, I support the draft plan. I am pleased that it is guided by best available science, public input, and Tribal engagement- the core tenets of the best way to protect, conserve, and sustain natural resources! Kitlyn Rescinito	Unknown	Feb162023	8:30:45	Proposed Wolf Management Plan	Hello, I am responding to your invitation to comment on wolf management plan. I scanned through the pages you included and did notice there were several deaths of various reasons/circumstances that were listed. One of the most important steps in any plan is to watch for poaching, and prosecute accordingly. While I do believe, alot of the stats you listed are for verification, I think an accurare wolf count is needed before implementing any management plan. And I don't believe you can justify removals by management under these circumstances. Many wolves are dispersing, to other States. Please include this in your list of stats. I hope you will consider all options and avenues, before removals. Thank You Best Regards, Kitlyn Rescinito
Jill Edwards	Y	Feb162023	13:29:28	DNR wolf plan survey	Hello. After reading the 2022 Wolf Management Plan, I just answered the survey. While the plan is pretty good and very complete, I found the survey to be basically useless. It should have had many, many more very specific questions. And I have a question. Within the last several years there was an extensive online survey about wolves. I saw no mention of the results of that survey in the management plan. What happened to those results? Jill Edwards Vilas County
Pat Clark	Y	Feb162023	13:41:57	Support for the Draft Wolf Management Plan	Dear Randy Johnson, Wolves need to become a protected species, permanently. The vast majority of WI citizens do not want them killed via hunting, trapping or hounding. Thank you and your team for the effort developing the 2022 draft Wisconsin Wolf Management Overall, I support the draft plan. I am pleased that it is guided by best available science, public input, and Tribal engagement- the core tenets of the best way to protect, conserve, and sustain natural resources! I also applaud the Department for conducting a very extensive and inclusive survey on the "public opinions regarding wolves in Wisconsin?. Things I support about the plan as written: ? The plan is reflective of the public opinions survey that finds opinions toward wolves have grown significantly more favorable. ? There is expressed commitment to science and continued research with partners and acknowledgement that ?keystone species such as wolves are an important component of a healthy ecosystem?. ? The plan outlines the strategies related to increasing public education related to the implementation of non-lethal conflict deterrent techniques. ? I support the plan?s recommendations to pursue more administrative rules, including the reduction of the window to report wolf kills to 8 hours or less and making the purposeful destruction of occupied wolf dens illegal Things I would like to see added or reviewed before plan is finalized: ? The plan should outline the concerns with ACT 169 and recommend legislative changes so that the DNR is able to make decisions on wolf stewardship in alignment with the goals of the wolf plan. ? A recommendation that the department issues wolf hunting licenses which are valid only in the specific wolf management zone(s) specified on the license. ? The DNR should better regulate hound training on wolves. The DNR should close wolf-focused hound training activities as each wolf hunting zone closes. The plan currently would allow hounds to chase wolves for training purposes during the wolf hunting season, across the entire state, until the very last wolf zone is closed. This could go on for months and would interfere with the wolf breeding season and population tracking of which both occur in late winter. ? There is currently no guidance in plan for next review or update ? Ideally, the plan should include a provision to update every 5-7 years rather than simply being ?valid until it is replaced.? ? There should be permanent, ongoing oversight by a stakeholder group AND a science committee to oversee wolf stewardship in Wisconsin. The stakeholder group must be inclusive and recognize the importance of Tribal oversight. ? I recommend identifying specific metrics that will define successful wolf management in Wisconsin. Examples should include metrics include pack integrity, average pack size, distribution of CWD in wolf range, the relative distribution of wolves across the state, and genetic connectivity and flow between packs across the state. ? The plan acknowledges that there are responsible farming practices and other non-lethal options to reduce wolf and livestock conflicts but should recommend that the DNR prioritizes these opportunities. Bottom line: Please continue to push for more science-based research in our state as well as wolf co-existence education across Wisconsin. Thank you for your consideration and careful work involving the on-going wolf stewardship of wolves in our state. Sincerely, Taylore Long [redacted] West Bend, WI 53090 [redacted] This message was sent by KnowWho, as a service provider, on behalf of an individual associated with Sierra Club. Brian Giles	Y	Feb162023	14:25:39	Support for the Draft Wolf Management Plan	Dear Randy Johnson, I believe we need a management plan that makes real sense like this one. There is much that needs to be taken into consideration and this one does. Thank you and your team for the effort developing the 2022 draft Wisconsin Wolf Management Overall, I support the draft plan. I am pleased that it is guided by best available science, public input, and Tribal engagement- the core tenets of the best way to protect, conserve, and sustain natural resources! I also applaud the Department for conducting a very extensive and inclusive survey on the "public opinions regarding wolves in Wisconsin?. Things I support about the plan as written: ? The plan removes a numeric population goal, allowing for an adaptable population: I support the goal of a self-sustaining, self-regulating, and genetically diverse wolf population that maintains connectivity with wolf populations in neighboring states and fulfills their ecological roles. ? The plan creates low limit zones around Tribal lands where the Tribes requested it: These lands are treaty-protected with documented wolf packs. Making this update is an important and welcome addition to the plan. Ideally, the plan would expand these zones beyond just the few that are listed and further reduce the limit to one wolf per subzone. ? The plan is reflective of the public opinions survey that finds opinions toward wolves have grown significantly more favorable. ? There is expressed commitment to science and continued research with partners and acknowledgement that ?keystone species such as wolves are an important component of a healthy ecosystem?. ? The plan outlines the strategies related to increasing public education related to the implementation of non-lethal conflict deterrent techniques. ? I support the plan?s recommendations to pursue more administrative rules, including the reduction of the window to report wolf kills to 8 hours or less and making the purposeful destruction of occupied wolf dens illegal Things I would like to see added or reviewed before plan is finalized: ? The plan should outline the concerns with ACT 169 and recommend legislative changes so that the DNR is able to make decisions on wolf stewardship in alignment with the goals of the wolf plan. ? Douglas Michalek	Y	Feb162023	15:49:27	Support for the Draft Wolf	Dear Randy Johnson, Wolves are an iconic animal that belongs on our landscape. They play an important role in the balance of the environment. From helping control CWD in the deer herd, too, helping to prevent over grazing by deer and other ungulates. The first and only time I saw wolves was in Alaska in 1984 never thinking that there would ever be a chance of

Name	Resident	Date	Time	Subject	Email Body
				Management Plan	seeing one in Wisconsin. They have made a dramatic recovery, just like the Bald Eagle and should be treated with the same respect. Unfortunately due to ignorance and just a general hate for wolves, there is a population of people that just want every wolf destroyed. Which is a shame. Wolves bring a certain wildness to our state and others. Every year for the last 5, I have gone camping in northern Minnesota, hoping to hear and see wolves. That was money spent that could have stayed in our state. Now that we have a viable population, there is a chance to see or hear one in Northern WI. Thank you and your team for the effort developing the 2022 draft Wisconsin Wolf Management Overall, I support the draft plan. I am pleased that it is guided by best available science, public input, and Tribal engagement- the core tenets of the best way to protect, conserve, and sustain natural resources! Patricia Balde	Y	Feb162023	17:38:02	Support for the Draft Wolf Management Plan	Dear Randy Johnson, Wolves are a vital part of the ecosystem they are less of a threat then coyotes. Bear hunters lie about the wolves to gain money from loss of their dogs they do not care about their dogs bear hunting with dogs is abuse for both dogs and bears. Hunters enter a wolf territory with their dogs and natures way tells the wolves to defend themselves. Wolves do not attack livestock like people say it is coyotes that do. Save the wolves Thank you and your team for the effort developing the 2022 draft Wisconsin Wolf Management Overall, I support the draft plan. I am pleased that it is guided by best available science, public input, and Tribal engagement- the core tenets of the best way to protect, conserve, and sustain natural resources! The plan is reflective of the public opinions survey that finds opinions toward wolves have grown significantly more favorable. ? There is expressed commitment to science and continued research with partners and acknowledgement that ?keystone species such as wolves are an important component of a healthy ecosystem?. ? The plan outlines the strategies related to increasing public education related to the implementation of non-lethal conflict deterrent techniques. ? I support the plan?s recommendations to pursue more administrative rules, including the reduction of the window to report wolf kills to 8 hours or less and making the purposeful destruction of occupied wolf dens illegal Things I would like to see added or reviewed before plan is finalized: ? The plan should outline the concerns with ACT 169 and recommend legislative changes so that the DNR is able to make decisions on wolf stewardship in alignment with the goals of the wolf plan. ? A recommendation that the department issues wolf hunting licenses which are valid only in the specific wolf management zone(s) specified on the license. ? The DNR should better regulate hound training on wolves. The DNR should close wolf-focused hound training activities as each wolf hunting zone closes. The plan currently would allow hounds to chase wolves for training purposes during the wolf hunting season, across the entire state, until the very last wolf zone is closed. This could go on for months and would interfere with the wolf breeding season and population tracking of which both occur in late winter. ? There is currently no guidance in plan for next review or update ? Ideally, the plan should include a provision to update every 5-7 years rather than simply being ?valid until it is replaced.? ? There should be permanent, ongoing oversight by a stakeholder group AND a science committee to oversee wolf stewardship in Wisconsin. The stakeholder group must be inclusive and recognize the importance of Tribal oversight. ? I recommend identifying specific metrics that will define successful wolf management in Wisconsin. Examples should include metrics include pack integrity, average pack size, distribution of CWD in wolf range, the relative distribution of wolves across the state, and genetic connectivity and flow between packs across the state. ? The plan acknowledges that there are responsible farming practices and other non-lethal options to reduce wolf and livestock conflicts but should recommend that the DNR prioritizes these opportunities. Bottom line: Please continue to push for more science-based research in our state as well as wolf co-existence education across Wisconsin. Thank you for your consideration and careful work involving the on-going wolf stewardship of wolves in our state. Sincerely, Laura Herzog [redacted] GLENDALE, WI 53217 [redacted] This message was sent by KnowWho, as a service provider, on behalf of an individual associated with Sierra Club. Scholze Rebecca	Y	Feb172023	11:08:50	Support for the Draft Wolf Management Plan	Dear Randy Johnson, Wolves are an important part of our ecosystem. They are an apex predator that has a role in controlling animal populations. When we take away a part of the chain, it breaks and becomes uncontrollable. Thank you and your team for the effort developing the 2022 draft Wisconsin Wolf Management Overall, I support the draft plan. I am pleased that it is guided by best available science, public input, and Tribal engagement- the core tenets of the best way to protect, conserve, and sustain natural resources! I also applaud the Department for conducting a very extensive and inclusive survey on the "public opinions regarding wolves in Wisconsin?. Things I support about the plan as written: ? The plan removes a numeric

Name	Resident	Date	Time	Subject	Email Body
					population goal, allowing for an adaptable population: I support the goal of a self-sustaining, self-regulating, and genetically diverse wolf population that maintains connectivity with wolf populations in neighboring states and fulfills their ecological roles. ? The plan creates low limit zones around Tribal lands where the Tribes requested it: These lands are treaty-protected with documented wolf packs. Making this update is an important and welcome addition to the plan. Ideally, the plan would expand these zones beyond just the few that are listed and further reduce the limit to one wolf per subzone. ? The plan is reflective of the public opinions survey that finds opinions toward wolves have grown significantly more favorable. ? There is expressed commitment to science and continued research with partners and acknowledgement that ?keystone species such as wolves are an important component of a healthy ecosystem?. ? The plan outlines the strategies related to increasing public education related to the implementation of non-lethal conflict deterrent techniques. ? Valerie Gibbons	Y	Feb172023	14:56:12	Support for the Draft Wolf Management Plan	Dear Randy Johnson, I am on the Wildlife Team of the Wisconsin Sierra Club and helped draft this letter regarding the Wolf Management Plan. In our best Wisconsin, there would be no authorized wolf kill. Wolves can manage themselves. Humans need to learn or be taught to manage their behaviors, wants, and needs rather than killing another mammal out of reprisal or fear. I am not Native American, but I see all animals as my fellow travelers. They have an inherent right to live unharmed by us. However, given where we are at, I applaud the science, public input and tribal engagement the plan takes into account. I would like to see more emphasis on nonlethal means of keeping wolves away from livestock and more education about the wonder of wolves. I especially would like to see the DNR take back its authority from the legislature by voicing concerns and pushing for changes to ACT 169, a terrible holdover from another decade. Let's stop the kill culture. Thank you and your team for the effort developing the 2022 draft Wisconsin Wolf Management Overall, I support the draft plan. I am pleased

C Tiefenthaler	Y	Feb172023	16:09:41	WISCONSIN DNR C/O Wolf Management Plan Comments	Comments regarding the Revised Wolf Management Plan: 1. The 1990 Plan wolf population was capped at 350 and was acceptable and passed the NRB approval et al. This number was and, still is, acceptable as a maximum wolf population in the State by the people, DNR, and USFWS. It also exceeds the minimum endangered species number/goal as defined by the USFWS. Keep this goal and state it clearly in the proposed draft plan. 2. Social Scientific Survey: People in Range understand what living with wolves means. Non-Range population figures mean nothing although interesting to look at. Those numbers should be weighted heavily in favor of Range population comments. I live in Boulder Junction! We are terrified to let our dog out day or night, take her for a walk, or even think about taking her on a snow shoe trail. I am always armed¦.that's fun. 3. Adaptive Wildlife Management The deer herd has been decimated in the North (and elsewhere) due to wolves¦.Period. What has changed since 1998 when, the 350 population goal was being discussed and the wolf population was estimated" by the experts at about 250? Now we have 1,134 or so, wolves in the State and the deer in the dense wolf areas are decimated. Has anyone been watching or analyzing this? Adaptive Wildlife Management for deer not wolves! 4. Translocatin wolves should not be allowed unless the population goes under 350 statewide. If that happens¦. the people in which the proposed translocation area must approve it¦. not at the will of the current DNR wolf manager. Before that would occur¦.problem wolves should be killed immediately. A Range landowner should be immediately issued a kill permit to facilitate the endeavor. 5. The five mile radius around Tribal boundaries for zero or reduced harvest should be eliminated¦. Period. 6. Increased harvesting of wolves in problem areas of repeated complaints must be a stated part of the Plan. A number of the stated goal must be listed in order to measure the effectiveness of the harvest. Thank you for your consideration of my comments. I can be reached at [redacted] for further discussion or questions. James E. Tiefenthaler, Jr. NRB member from 1990-2003
Kristine Jensch	Y	Feb172023	16:16:30	Support for the Draft Wolf Management Plan	Dear Randy Johnson, Wolves are living, sentient beings. Thank you for revising your new draft plan that I hope will prevent the conditions hat led to the disastrous hunt a couple of years ago. Never Again. Thanks for listening - and continuing to listen, to the community, to base the plan on science and with consideration for the wolf?s place in Tribal culture. I would like to think we would never have another hunt. I would hope that another one would not happen for a few years, to give the population time to recover a bit. I?m glad the plan doesn?t base the hunt on numbers. I would like to think that outside interests from other states not have a voice in this plan. But thank you for what you are doing. Thank you and your team for the effort developing the 2022 draft Wisconsin Wolf Management Overall, I support the draft plan. I am pleased that it is guided by best available science, public input, and Tribal engagement- the core tenets of the best way to protect, conserve, and sustain natural resources! I also applaud the Department for conducting a very extensive and inclusive survey on the "public opinions regarding wolves in Wisconsin?. Things I support about the plan as written: ? The plan removes a numeric population goal, allowing for an adaptable population: I support the goal of a self-sustaining, self-regulating, and genetically diverse wolf population that maintains connectivity with wolf populations in neighboring states and fulfills their ecological roles. ? The plan creates low limit zones around Tribal lands where the Tribes requested it: These lands are treaty-protected with documented wolf packs. Making this update is an important and welcome addition to the plan. Ideally, the plan would expand these zones beyond just the few that are listed and further reduce the limit to one wolf per subzone. ? The plan is reflective of the public opinions survey that finds opinions toward wolves have grown significantly more favorable. ? There is expressed commitment to science and continued research with partners and acknowledgement that ?keystone species such as wolves are an important component of a healthy ecosystem?. ? The plan outlines the strategies related to increasing public education related to the implementation of non-lethal conflict deterrent techniques. ? I support the plan?s recommendations to pursue more administrative rules, including the reduction of the window to report wolf kills to 8 hours or less and making the purposeful destruction of occupied wolf dens illegal Things I would like to see added or reviewed before plan is finalized: ? The plan should outline the concerns with ACT 169 and recommend legislative changes so that the DNR is able to make decisions on wolf stewardship in alignment with the goals of the wolf plan. ? A recommendation that the department issues wolf hunting licenses which are valid only in the specific wolf management zone(s) specified on the license. ? The DNR should better

Kim Kreimann	Y	Feb172023	22:57:53	Support for the Draft Wolf Management Plan	Dear Randy Johnson, This matters to me because I believe we are caretakers of God?s creation. Everything was made by Him and for Him according to the Bible. We need to do our best and base decisions on ecological impact and rather than barstool opinions and politics. This new plan is a big step in the right direction. I do believe we need to end compensation for hounds lost to wolves and instead use these funds to help farmers implement wolf deterrents. People who run hounds know the risks and they should not be rewarded for putting their dogs in harms way. If someone drives a vehicle out on a lake to go ice fishing and the vehicle falls through the ice we don?t compensate them. It?s basically the same thing with hounders running dogs in wolf territory, it?s their hobby, it?s their risk. Thank you and your team for the effort developing the 2022 draft Wisconsin Wolf Management Overall, I support the draft plan. I am pleased that it is guided by best available science, public input, and Tribal engagement- the core tenets of the best way to protect, conserve, and sustain natural resources! The plan is reflective of the public opinions survey that finds opinions toward wolves have grown significantly more favorable. ? There is expressed commitment to science and continued research with partners and acknowledgement that ?keystone species such as wolves are an important component of a healthy ecosystem?. ? The plan outlines the strategies related to increasing public education related to the implementation of non-lethal conflict deterrent techniques. ? I support the plan?s recommendations to pursue more administrative rules, including the reduction of the window to report wolf kills to 8 hours or less and making the purposeful destruction of occupied wolf dens illegal Things I would like to see added or reviewed before plan is finalized: ? The plan should outline the concerns with ACT 169 and recommend legislative changes so that the DNR is able to make decisions on wolf stewardship in alignment with the goals of the wolf plan. ? A recommendation that the department issues wolf hunting licenses which are valid only in the specific wolf management zone(s) specified on the license. ? The DNR should better regulate hound training on wolves. The DNR should close wolf-focused hound training activities as each wolf hunting zone closes. The plan currently would allow hounds to chase wolves for training purposes during the wolf hunting season, across the entire state, until the very last wolf zone is closed. This could go on for months and would interfere with the wolf breeding season and population tracking of which both occur in late winter. ? There is currently no guidance in plan for next review or update ? Ideally, the plan should include a provision to update

					every 5-7 years rather than simply being ?valid until it is replaced.? ? There should be permanent, ongoing oversight by a stakeholder group AND a science committee to oversee wolf stewardship in Wisconsin. The stakeholder group must be inclusive and recognize the importance of Tribal oversight. ? I recommend identifying specific metrics that will define successful wolf management in Wisconsin. Examples should include metrics include pack integrity, average pack size, distribution of CWD in wolf range, the relative distribution of wolves across the state, and genetic connectivity and flow between packs across the state. ? The plan acknowledges that there are responsible farming practices and other non-lethal options to reduce wolf and livestock conflicts but should recommend that the DNR prioritizes these opportunities. Bottom line: Please continue to push for more science-based research in our state as well as wolf co-existence education across Wisconsin. Thank you for your consideration and careful work involving the on-going wolf stewardship of wolves in our state. Deb Lukasik	Y	Feb182023	8:47:53	Support for the Draft Wolf Management Plan	Dear Randy Johnson, Wolves are part of the life cycle of all animals and a gift demo God. You dont have to kill animals for the sake of killing. They are part of nature's ecobalance. Thank you and your team for the effort developing the 2022 draft Wisconsin Wolf Management Overall, I support the draft plan. I am pleased that it is guided by best available science, public input, and Tribal engagement- the core tenets of the best way to protect, conserve, and sustain natural resources! I also applaud the Department for conducting a very extensive and inclusive survey on the "public opinions regarding wolves in Wisconsin?. Things I support about the plan as written: ? The plan removes a numeric population goal, allowing for an adaptable population: I support the goal of a self-sustaining, self-regulating, and genetically diverse wolf population that maintains connectivity with wolf populations in neighboring states and fulfills their ecological roles. ? The plan creates low limit zones around Tribal lands where the Tribes requested it: These lands are treaty-protected with documented wolf packs. Making this update is an important and welcome addition to the plan. Ideally, the plan would expand these zones beyond just the few that are listed and further reduce the limit to one wolf per subzone. ? The plan is reflective of the public opinions survey that finds opinions toward wolves have grown significantly more favorable. ? There is expressed commitment to science and continued research with partners and acknowledgement that ?keystone species such as wolves are an important component of a healthy ecosystem?. ? Patricia Nadreau	Y	Feb182023	12:07:03	Support for the Draft Wolf Management Plan	Dear Randy Johnson, The Trump administration moved to remove wolves from the Endangered Species list in October. Wolves are important animals to our ecosystems and are important to the Ojibwe Tribe. No wolf hunt should occur until there is an inclusive, fair, and science-based planning process. Wisconsin is the only state to allow wolves to be killed using dogs, which resulted in many heinous practices. It embarasses me to have to tell people I am from Wisconsin when I see things like this happening here. We need a new draft plan that centers on science, public input, and Tribal engagement- the core tenets of the best way to protect, conserve, and sustain natural resources. Thank you and your team for the effort developing the 2022 draft Wisconsin Wolf Management Overall, I support the draft plan. I am pleased that it is guided by best available science, public input, and Tribal engagement- the core tenets of the best way to protect, conserve, and sustain natural resources!
