It's hard to believe when you look at them, but whales used to have legs!

Their ancestors were creatures that lived on land 50 million years ago, after the dinosaurs but before the appearance of humans.

The Pakicetus was a doglike creature about the size of a goat that had four legs. As whales gradually evolved over millions of years, their front legs became flippers and their hind legs disappeared.

The fact that the whales of today still have pelvic bones is evidence of this dramatic transformation.

Find five things associated with seas and oceans in today's paper.

Use the News

Write down the first letter of each pictured object. When completed, the letters on the wheel will spell out the name of the closest living animal related to the whale.

Answer: HIPPOPOTAMUS
